

Designation: D4328 - 18

Standard Practice for Calculation of Supersaturation of Barium Sulfate, Strontium Sulfate, and Calcium Sulfate Dihydrate (Gypsum) in Brackish Water, Seawater, and Brines¹

This standard is issued under the fixed designation D4328; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice covers the calculation of supersaturation of barium sulfate, strontium sulfate, and calcium sulfate dihydrate (gypsum) in brackish water, seawater, and brines in which barium, strontium, and calcium ions either coexist or exist individually in solution in the presence of sulfate ions.

1.2 This practice is not applicable for calculating calcium sulfate dihydrate supersaturation if the temperatures of saline waters under investigation exceed 95°C. At temperatures above 95°C, hemianhydrate and anhydrite would be major insoluble forms.

1.3 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.4 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety, health, and environmental practices and determine the applicability of regulatory limitations prior to use.

1.5 This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.

3. Terminology

3.1 Definitions:

3.1.1 For definitions of terms used in this standard, refer to Terminology D1129.

4. Significance and Use

4.1 This practice covers the mathematical calculation of the supersaturation of three principal sulfate scaling compounds found in industrial operations. Application of this standard practice to the prediction of scale formation in a given system, however, requires experience. The calculations tell the user if a water, or mixture of waters, is in a scaling mode. Whether or not scale will in fact form, how quickly it will form, where it will form, in what quantities, and what composition are subject to factors beyond the scope of this practice. However, based on how supersaturated a given water or mixture of waters is, an objective evaluation of the relative likelihood of scale formation can be made.

Note 1—There are several personal computer (PC) type programs that are both available commercially and publicly that will perform these calculations.

5. Procedure

5.1 Collect water samples for compositional analysis in accordance with Practices D3370.

¹ This practice is under the jurisdiction of ASTM Committee D19 on Water and is the direct responsibility of Subcommittee D19.05 on Inorganic Constituents in Water.

Current edition approved May 1, 2018. Published May 2018. Originally approved in 1984. Last previous edition approved in 2013 as D4328 – 08 (2013). DOI: 10.1520/D4328-18.

🖽 D4328 – 18

5.2 Determine the calcium and magnesium concentrations in accordance with Test Methods D511.

5.3 Determine the barium concentration in accordance with Test Methods D3651 or D3986.

5.4 Determine the strontium concentration in accordance with Test Method D3352.

5.5 Determine sodium and potassium concentrations in accordance with Test Method D3561.

5.6 Determine sulfate ion concentration in accordance with Test Method D516.

5.7 Determine chloride ion concentration in accordance with Test Methods D512.

5.8 Determine carbonate and bicarbonate ion concentrations in accordance with Test Methods D513.

5.9 Determine the concentrations of all other major inorganic constituents that may be present in the water under investigation in accordance with appropriate test methods in *Annual Book of ASTM Standards*, Vols 11.01 and 11.02.

5.10 Determine temperature and pressure of the water system under investigation.

6. Calculation of Ionic Strength

6.1 Calculate the ionic strength of the water under investigation as follows:

 $\mu = \frac{1}{2} \sum C_i Z_i^2 \mathbf{D} \mathbf{S}^* / \mathbf{S} \mathbf{T} \mathbf{A}^{(1)} \mathbf{A}$

where:

$$\mu$$
 = ionic strength,

 C_i = molal concentration of each ion in solution, and

 Z_i = charge number of ion, i.

7. Calculation of Barium Sulfate Supersaturation (Refer to Appendix X1)

7.1 Calculate barium sulfate solubility in the water under investigation, using the equation as follows:

$$S = \left(\sqrt{X^2 + 4K} - X\right)/2\tag{2}$$

where:

- *S* = solubility, moles of solute per kilogram of water corrected for the common ion effect,
- K = solubility product constant (molal) at the ionic strength, temperature and pressure of the water under investigation. For BaSO₄ refer to Appendix X2, and
- X =molal excess of soluble common ion.

7.2 Calculate the amount of barium sulfate, moles per kilogram of water, in the sample based on the lesser of the barium or sulfate ion concentration.

7.3 If the amount of $BaSO_4$ in the sample (7.2) is less than its calculated solubility (7.1), the water in question is undersaturated with respect to $BaSO_4$. If the amount of $BaSO_4$ present is greater than its solubility, the water is supersaturated with respect to $BaSO_4$. Calculate the amount of supersaturation as the difference between the two values:

$$supersaturation = concentration - solubility$$
 (3)

Note 2—Supersaturation may also be calculated directly from the equation (1).³

$$([Ba^{++}] - y)([SO_4 =] - y) = K$$
 (4)

where:

Ba $^{2+}$ = concentration of barium, molal,

- SO_4^{2-} = concentration of sulfate, molal,
 - = excess (supersaturation) of $BaSO_4$, molal, and
- K = solubility product constant (molal) of BaSO₄ at test conditions.

The value *X* may then be determined from the quadratic equation (see Appendix X1):

$$X = \frac{-B \pm \sqrt{B^2 - 4AC}}{2A} \tag{5}$$

Report $BaSO_4$ supersaturation in molal terms of the weight of $BaSO_4$ per volume of water, mg/L.

$$BaSO_4$$
 supersaturation, mg/L (6)

$$= \operatorname{BaSO}_{4}, (\operatorname{molal}^{2}) \times 10^{3} \times 233 \times \left(\begin{array}{c} \frac{1000 \times D}{TDS} + 1000 \\ \frac{TDS}{1000} \end{array}\right)$$

where:

$$D = \text{sample density.}$$

8. Calculation of Strontium Sulfate Supersaturation (Refer to Appendix X1)

8.1 Calculate strontium sulfate solubility using the same steps described for $BaSO_4$ (Section 7), but substituting the appropriate values for $SrSO_4$ in Eq 2 (refer to Appendix X3 or Appendix X4).

Note 3—If barium sulfate supersaturation exists, the amount of sulfate available for strontium sulfate will be less by the amount of sulfate equivalent to the calculated $BaSO_4$ supersaturation.

Note 4—If carbonate ions are present, strontium carbonate may precipitate. The amount of strontium may then be corrected by that required for strontium carbonate precipitation prior to the calculation of $SrSO_4$ solubility (2). Practically speaking, however, due to the extremely low solubility of $SrCO_3$, this correction may usually be omitted.

8.2 Calculate the amount of strontium sulfate moles per kilogram water in the sample based on the lesser of the strontium or remaining sulfate ion concentration.

8.3 If the amount of $SrSO_4$ in the sample (8.2) is less than its calculated solubility (8.1), the water in question is undersaturated with respect to $SrSO_4$. If the amount of $SrSO_4$ present is greater than its solubility, the water is supersaturated with respect to $SrSO_4$. Calculate the amount of supersaturation, moles per kilogram water by difference (Eq 3), or by substituting appropriate data in Eq 4 (Note 2).

8.3.1 Report $SrSO_4$ supersaturation in terms of the weight of $SrSO_4$ per volume of water as follows:

$$SrSO_4$$
 supersaturation mg/L (7)

$$= SrSO_4, \text{ (molal)} \times 10^3 \times 184 \times \left(\frac{1000 \times D}{\frac{TDS}{1000} + 1000} \right)$$

³ The boldfaced numbers in parentheses refer to a list of references at the end of this standard.

9. Calculation of Calcium Sulfate Supersaturation (Refer to Appendix X1)

9.1 Calculate calcium sulfate solubility using the same steps described for $BaSO_4$ (Section 7), but substituting the appropriate values for $CaSO_4$ in Eq 2 (refer to Appendix X5).

9.2 Calculate the amount of calcium sulfate moles per kilogram in the sample based on the lesser of the calcium or remaining sulfate ion.

9.3 If the amount of $CaSO_4$ in the sample (9.2) is less than its calculated solubility (9.1), the water in question is undersaturated with respect to CaSO₄. If the amount of CaSO₄ present is greater than its solubility, the water is supersaturated with respect to CaSO₄. Calculate the amount of supersaturation moles per kilogram by difference (Eq 3) or by substituting appropriate data in Eq 4 (Note 2).

9.3.1 Report CaSO₄ supersaturation in terms of the weight of CaSO₄·2H₂O (gypsum) per volume of water after converting moles per data obtained above to mg/L as follows:

> CaSO·2H₂O supersaturation, mg/L (8)

=
$$CaSO_4 \cdot 2H_2O_2$$
, moles/kg × 172.17 × 10³ × D

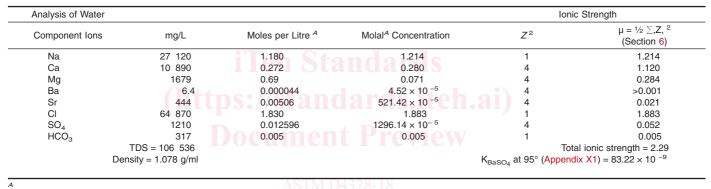

10. Keywords

10.1 barium sulfate; brines; calcium sulfate dihydrate; strontium sulfate

APPENDIXES

(Nonmandatory Information)

X1. SAMPLE CALCULATION OF BaSO₄ SUPERSATURATION AT 95°C

1000 Convert moles/L to molal = moles/L × TDS

1000 = moles/L imes $\frac{1078 - 106.5}{1078 - 106.5}$ = moles/L \times 1.029

 $(Sp gr \times 1000) -$

X1.1 $BaSO_4$ Solubility (Refer to 7.1):

$$S = \left(\sqrt{X^2 + 4K} - X\right)/2$$

where:

X = molal excess of common ion (in this case SO_4),

 $= (1296.14 \times 10^{-5}) - (4.52 \times 10^{-5})$ X $= 1291.62 \times 10^{-5}$ 4K $= 4(83.22 \times 10^{-9}) = 332.88 \times 10^{-9}$, or 3328.8×10^{-10} $= \left[\sqrt{(1291.62 \times 10^{-5})^2 + (3328.8 \times 10^{-10})} \right]$ S $-(1291.62 \times 10^{-5})]/2$

Solubility $S = 0.644 \times 10^{-5}$ molal

X1.2 $BaSO_4$ Present (Refer to 7.2):

1000

X1.2.1 Ba present = 4.52×10^{-5} molal

X1.2.2 SO₄ present = 1296.14×10^{-5} molal

X1.2.3 Based on lower value (Ba), BaSO₄ present = 4.52×10^{-5} molal

X1.3 Amount of $BaSO_4$ Supersaturation (Refer to 7.3):

X1.3.1 BaSO₄ present based on $Ba^{2+} = 4.52 \times 10^{-5}$ molal

X1.3.2 Calculated BaSO₄ solubility, $S = 0.64 \times 10^{-5}$ molal

X1.3.3 BaSO₄ excess; that is, supersaturation = 3.88×10^{-5} molal; or 8.8 mg/L of sample
