This document is not an ASTM standard and is intended only to provide the user of an ASTM standard an indication of what changes have been made to the previous version. Because it may not be technically possible to adequately depict all changes accurately, ASTM recommends that users consult prior editions as appropriate. In all cases only the current version of the standard as published by ASTM is to be considered the official document.

Designation: D6645 - 01 (Reapproved 2010) D6645 - 18

Standard Test Method for Methyl (Comonomer) Content in Polyethylene by Infrared Spectrophotometry¹

This standard is issued under the fixed designation D6645; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope Scope*

1.1 This test method covers the determination of methyl groups (that is, comonomer content) in polyethylenes by infrared spectrophotometry. The test method is applicable to copolymers of ethylene with 1-butene, 1-hexene, or 1-octene having densities above 900 kg/m³. High-pressure low-density polyethylenes (LDPE) and terpolymers are excluded.

1.2 The values stated in SI units, based on IEEE/ASTM SI-10, are to be regarded as the standard.

1.3 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety safety, health, and healthenvironmental practices and determine the applicability of regulatory limitations prior to use.

NOTE 1-There is no known ISO equivalent to this standard.

<u>1.4 This international standard was developed in accordance with internationally recognized principles on standardization</u> established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.

3. Terminology

3.1 *Terminology*—The units, symbols, and abbreviations used in this test method appear in Terminology E131 or IEEE/ ASTM SI-10.

3.2 comonomer—α-olefin monomer. In this test method, comonomer refers to 1-butene, 1-hexene, and or 1-octene only.

4. Summary of Test Method

4.1 The band located between 1377 cm⁻¹ and 1379 cm⁻¹ is due to a deformation vibration of the $-CH_3$ group. Bands at approximately 772 cm⁻¹ (branch methylene rocking mode), 895 cm⁻¹ (methyl rocking mode), and 785 cm⁻¹ (branch methylene rocking mode) are characteristic of <u>an</u> ethyl <u>branch</u> (that is, butene copolymer), <u>a</u> butyl <u>branch</u> (that is, hexene copolymer), and <u>a</u> hexyl <u>branch</u> (that is, octene copolymer) branches, copolymer), respectively.³

4.2 This test method determines the methyl <u>group</u> (that is, comonomer) content of a polyethylene copolymer based on the IR absorbance at 1378 cm⁻¹ from a pressed plaque. The comonomer type has to be known and a calibration curve has to be available prior to the analysis. If the comonomer is not known a priori, the presence of bands at 772 cm⁻¹, 895 cm⁻¹, and 785 cm⁻¹ can be used to identify ethyl (minimum of 1 branch per 1000 carbons), butyl (minimum of about 5 branches per 1000 carbons), and hexyl (minimum of about 5 branches per 1000 carbons) branches, respectively. A more sensitive and less ambiguous identification is obtained by C13 NMR spectroscopy. The latter technique is also used as a reference technique to provide polymer standards for the generation of IR calibration curves.

NOTE 2—For commonder identification, maximum sensitivity, it is recommended, for maximum sensitivity, recommended to view the second derivative of the IR spectrum. spectrum to identify the common type.

4.3 The method is calibrated by plotting absorbance at 1378 cm⁻¹ per unit area of the methylene combination band at 2019 cm⁻¹ (that is, internal thickness correction approach) or per unit of spectral cross-section (that is, the reciprocal of the product of plaque thickness and density) versus number of branches per 1000 carbons as determined by C13 NMR spectroscopy. Although both approaches give equivalent results, the one using internal thickness correction is recommended in this test method since it is considerably simpler to execute.

5. Significance and Use

5.1 This method determines the number of branches (that is, comonomer content) in copolymers of ethylene with 1-butene, 1-hexene or 1-octene. This information can be correlated with physical properties such as melting point, density, and stiffness, all of which depend on the degree of crystallinity of the polymer. Differences in the comonomer content thus maycan have a significant effect on the final properties of products made from these resins.

6. Interferences

6.1 A conformational CH_2 wagging absorbance at 1368 cm⁻¹ overlaps the methyl absorbance at 1378 cm⁻¹, but does not cause significant interference in this test method since its intensity is not significantly affected by the comonomer content, but rather by the plaque thickness. The result of not correcting for this overlap is a positive ordinate intercept for the calibration curve (see 10.4). Another conformational CH_2 wagging absorbance at 1352 cm⁻¹ does not significantly overlap the 1378 cm⁻¹ absorbance.

6.2 The presence of most pigments will interfere with this method.

6.3 The presence of low molecular weight hydrocarbons will produce high results in this method due to absorbance by their end methyl groups at 1378 cm⁻¹.

6.4 The secondary antioxidant Irgafos 168^4 shows an absorbance at 768 cm⁻¹ which interferes with the identification of low levels (that is, typically less than 5 branches per 1000 carbons or less) of ethyl branches.

6.5 Vinylidene groups absorb at 888 cm⁻¹ and thus $\frac{\text{may}_{can}}{\text{may}_{can}}$ interfere with a conclusive identification of a hexene copolymer from its 895 cm⁻¹ resonance, depending on the relative intensities of the two peaks.

7. Apparatus

7.1 Infrared Spectrophotometer, either double beam or a Fourier transform (FTIR).

7.1.1 *Dispersive Infrared Spectrophotometer*, capable of achieving a spectral bandwidth of 4 cm⁻¹ (see Practice E932). The instrument shouldmust be capable of scale expansion along the wavenumber axis.

7.1.2 Fourier Transform Infrared Spectrometer, capable of 4 cm⁻¹ resolution (see Practice E1421). The instrument should<u>must</u> be capable of scale expansion along the wavenumber axis.

7.2 Compression Molding Press, with platens capable of being heated to 180°C.

- 7.3 Two Metal Plates, 150 by 150 mm or larger, of 0.5-mm thickness with smooth surfaces.
- 7.4 Brass Shims, approximately 75 by 75 mm, of 0.3 mm thickness with an aperture in the center at least 25 by 38 mm.
- 7.5 Micrometer (optional), with thimble graduations of 0.001 mm.

7.6 Film Mounts, with apertures at least 6 by 27 mm, to hold the specimens in the infrared spectrophotometer.
