

Designation: D5587 – 15 (Reapproved 2019)

Standard Test Method for Tearing Strength of Fabrics by Trapezoid Procedure¹

This standard is issued under the fixed designation D5587; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the measurement of the tearing strength of textile fabrics by the trapezoid procedure using a recording constant-rate-of-extension-type (CRE) tensile testing machine.

1.1.1 The CRE-type tensile testing machine has become the preferred test apparatus for determining trapezoid tearing strength. It is recognized that some constant-rate-of-traverse-type (CRT) tensile testing machines continue to be used. Consequently, these test instruments may be used when agreed upon between the purchaser and the supplier. The conditions for use of the CRT-type tensile tester are included in [Appendix X1](#).

1.2 This test method applies to most fabrics including woven fabrics, air bag fabrics, blankets, napped fabrics, knitted fabrics, layered fabrics, pile, and nonwoven fabrics. The fabrics may be untreated, heavily sized, coated, resin-treated, or otherwise treated. Instructions are provided for testing specimens with or without wetting.

1.3 Tearing strength, as measured in this test method, requires that the tear be initiated before testing. The reported value obtained is not directly related to the force required to initiate or start a tear.

1.4 Two calculations for trapezoid tearing strength are provided: the single-peak force and the average of five highest peak forces.

1.5 The values stated in SI units are to be regarded as the standard. The values stated in inch-pound units may be approximate.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety, health, and environmental practices and determine the applicability of regulatory limitations prior to use.*

1.7 *This international standard was developed in accordance with internationally recognized principles on standard-*

ization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.

3. Terminology

3.1 For all terminology relating to D13.59, Fabric Test methods, General, refer to Terminology [D4850](#).

3.1.1 The following terms are relevant to this standard: fabric, in textiles; peak force, in tear testing of fabrics; tearing force, in fabric; tearing strength, in fabrics; yarn distortion (see [Fig. 1](#)).

3.2 For all other terms related to textiles, refer to Terminology [D123](#).

4. Summary of Test Method

4.1 An outline of an isosceles trapezoid is marked on a rectangular specimen (see [Fig. 2](#)). The specimen is slit at the center of the smallest base of the trapezoid to start the tear. The nonparallel sides of the marked trapezoid are clamped in parallel clamps of a tensile testing machine. The separation of the clamps is increased continuously to apply a force to propagate the tear across the specimen. At the same time, the

force developed is recorded. The force to continue the tear is calculated from autographic chart recorders or microprocessor data collection systems.

5. Significance and Use

5.1 This test method is considered satisfactory for acceptance testing of commercial shipments because current estimates of between-laboratory precision are acceptable, and this test method is used extensively in the trade for acceptance testing.

5.2 If there are differences of practical significance between test results for two laboratories (or more), comparative test should be performed to determine if there is a statistical bias between them, using competent statistical assistance. As a minimum, use the samples for such a comparative test that are as homogeneous as possible, drawn from the same lot of material as the samples that resulted in disparate results during initial testing. Randomly assign the samples in equal numbers to each laboratory. The test results from the laboratories involved should be compared using a statistical test for unpaired data, at a probability level chosen prior to the testing series. If bias is found, either its cause must be found and corrected, or future test results for that material must be adjusted in consideration of the known bias.

5.3 The trapezoid tear produces tension along a reasonably defined course such that the tear propagates across the width of the specimen. It is useful for estimating the relative tear resistance of different fabrics or different directions in the same fabric.

5.4 Depending on the nature of the specimen, the data recording devices will show the tearing force in the form of a peak or peaks. The highest peaks appear to reflect the strength of the yarn components, individually or in combination, needed to stop a tear in fabrics of the same construction. The valleys recorded between the peaks have no specific significance. The minimum tearing force, however, is indicated to be above the lowest valleys.

5.5 Most textile fabrics can be tested by this test method. Some modification of clamping techniques may be necessary for a given fabric, depending upon its structure. Strong fabrics or fabrics made from glass fibers require special adaptation to prevent them from slipping in the clamps or being damaged as a result of being gripped in the clamps. In some cases, due to fabric constructions, individual yarns may not rupture but show a high peak and yarn distortion within the test specimen. Wherever possible, this shall be prevented. If you have tried all of these steps and yarn distortion still occurs, this must be included in the report.

5.6 The CRE-type is the preferred tensile testing machine. This test method allows the use of the CRT-type tensile machine when agreed upon between the purchaser and the supplier. There may be no overall correlation, however, between the results obtained with the CRT-type machine and the CRE-type machine. Consequently, these two tensile testers cannot be used interchangeably unless the degree of quantitative correlation has been established between the purchaser and the supplier. In any event, the CRE-type machine shall prevail.

6. Apparatus

6.1 *Tensile Testing Machine*⁴, of the CRE-type conforming to the requirements of Specification **D76** with autographic recorder, or automatic microprocessor data gathering system.

6.2 *Clamps*, having all clamping surfaces parallel, and capable of preventing slipping of the fabric specimen during a test, and measuring at least 50 by 75 mm (at least 2 by 3 in.), with the longer dimension perpendicular to the direction of application of the force.

6.2.1 Hydraulic or pneumatic clamping systems with a minimum of 50 by 75-mm (at least 2 by 3-in.) rubber, metal, or padded/coated clamps faces shall be used. The faces shall have an appropriate clamping force at the clamp faces depending on the type of fabric under test. The pressure should be sufficient to prevent slippage of the fabric specimen from the clamps during the test, while ensuring the specimen is not damaged at the clamps edge. For certain industrial type fabrics a gripping force at the clamps of 13 to 14 kN (2900 to 3111 lbf) is recommended. Manual clamping is permitted providing no fabric specimen slippage in the clamp is observed. When using manual clamping, use of torque wrench or other tool is recommended to consistently achieve 2900–3111 lbf.

6.2.2 For some fabrics, to prevent fabric slippage or yarn distortion from the clamp when using clamp faces other than serrated, such as rubber faced clamps, the clamps faces may be covered with a No. 80 to 120 medium grit emery cloth. Secure the emery cloth to the clamps faces with pressure-sensitive tape. Other techniques may also be used such as resins if necessary. If fabric slippage or yarn distortion continues to occur, then serrated or interlocking clamps faces should be used.

6.3 *Cutting Die or Template*, having essentially the shape and dimensions shown in **Fig. 2**.

⁴ Apparatus and accessories are commercially available.

FIG. 2 Templates for Cutting and Marking Trapezoid Test Specimens (mm)

TABLE 1 Number of Rolls or Pieces of Fabric in the Lot Sample

Number of Rolls or Pieces in Lot, Inclusive	Number of Rolls or Pieces in Lot Sample
1 to 3	all
4 to 24	4
25 to 50	5
over 50	10 % to a maximum of 10 rolls or pieces

7. Sampling and Test Specimens

7.1 Lot Sample—As a lot sample for acceptance testing, randomly select the number of rolls or pieces of fabric directed in an applicable material specification or other agreement between the purchaser and the supplier. Consider the rolls or pieces of fabric to be the primary sampling units. In the absence of such an agreement, take the number of fabric rolls specified in Table 1.

NOTE 1—An adequate specification or other agreement between the purchaser and the supplier requires taking into account the variability between rolls or pieces of fabric and between specimens from a swatch from a roll or piece of fabric to provide a sampling plan with a meaningful producer’s risk, consumer’s risk, acceptable quality level, and limiting quality level.

7.2 Laboratory Sample—For acceptance testing, take a swatch extending the width of the fabric and approximately 1 m (1 yd) along the machine direction from each roll or piece in the lot sample. For rolls of fabric, take a sample that will exclude fabric from the outer wrap of the roll or the inner wrap around the core of the roll of fabric.

7.2.1 Stretch Fabrics—For fabrics with stretch yarns, laboratory samples shall be allowed to relax lying flat for 24 h in the conditioned atmosphere outlined in Section 9. Once relaxed, samples are to be marked and cut as described above.

7.3 Test Specimens—From each laboratory sampling unit, take five specimens from the machine direction and five specimens from the cross-machine direction, for each test condition described in 9.1 and 9.2, as applicable to a material specification or contract order.

7.3.1 Direction of Test—Consider the long direction as the direction of test.

7.3.2 Cutting Test Specimens—Take the specimens to be used for the measurement of machine direction with the longer dimension parallel to the machine direction. Take the speci-

mens to be used for the measurement of the cross-machine direction with the longer dimension parallel to the cross-machine direction. When specimens are to be tested wet, take the specimens from areas adjacent to the dry test specimens. Label to maintain specimen identity.

7.3.2.1 In cutting the woven fabric specimens, take care to align the yarns running in the short direction parallel with the die such that when the slit is cut, the subsequent tear will take place between these yarns and not across them. This precaution is most important when testing bowed fabrics.

7.3.2.2 Cut specimens representing a broad distribution across the width and length, preferably along the diagonal of the laboratory sample, and no nearer the edge than one tenth its width. Ensure specimens are free of folds, creases, or wrinkles. Avoid getting oil, water, grease, and so forth, on the specimens when handling.

7.3.2.3 Use the cutting die or template described in 6.3 and shown in Fig. 2. Mark each specimen with an isosceles trapezoid template (see Fig. 2). Make a preliminary cut 15 mm (0.625 in.) long at the center of the 25-mm (1-in.) edge, as shown in Fig. 2.

NOTE 2—Tests were carried out in 2007 to evaluate whether the specimen size and clamps separation could be increased to facilitate easier loading of the specimen. It was found that this caused a difference in the final results depending on the fabric type. Therefore, it is not possible to increase the specimen size.
