INTERNATIONAL ELECTROTECHNICAL COMMISSION

ELECTRICAL INSTALLATIONS OF BUILDINGS –

Part 4-44: Protection for safety – Protection against voltage disturbances and electromagnetic disturbances

FOREWORD

1) The IEC (International Electrotechnical Commission) is a worldwide organization for standardization comprising all national electrotechnical committees (IEC National Committees). The object of the IEC is to promote international co-operation on all questions concerning standardization in the electrical and electronic fields. To this end and in addition to other activities, the IEC publishes International Standards. Their preparation is entrusted to technical committees; any IEC National Committee interested in the subject dealt with may participate in this preparatory work. International, governmental and non-governmental organizations liaising with the IEC also participate in this preparation. The IEC collaborates closely with the International Organization for Standardization (ISO) in accordance with conditions determined by agreement between the two organizations.
2) The formal decisions or agreements of the IEC on technical matters express, as nearly as possible, an international consensus of opinion on the relevant subjects since each technical committee has representation from all interested National Committees.
3) The documents produced have the form of recommendations for international use and are published in the form of standards, technical specifications, technical reports or guides and they are accepted by the National Committees in that sense.
4) In order to promote international unification, IEC National Committees undertake to apply IEC International Standards transparently to the maximum extent possible in their national and regional standards. Any divergence between the IEC Standard and the corresponding national or regional standard shall be clearly indicated in the latter.
5) The IEC provides no marking procedure to indicate its approval and cannot be rendered responsible for any equipment declared to be in conformity with one of its standards.
6) Attention is drawn to the possibility that some of the elements of this International Standard may be the subject of patent rights. The IEC shall not be held responsible for identifying any or all such patent rights.

International Standard IEC 60364-4-44 has been prepared by IEC technical committee 64: Electrical installations and protection against electric shock.

The IEC 60364 series (parts 1 to 6), is currently being restructured, without any technical changes, into a more simple form (see annex C).

According to a unanimous decision by the Committee of Action (CA/1720/RV (2000-03-21)), the restructured parts of IEC 60364 have not been submitted to National Committees for approval.

The text of this first edition of IEC 60364-4-44 is compiled from and replaces

– part 4-442, first edition (1993), its amendment 1 (1995) and its amendment 2 (1999)
– part 4-443, second edition (1995) and its amendment 1 (1998),
– part 4-444, first edition (1996) and
– part 4-45, first edition (1984).

This publication has been drafted, as close as possible, in accordance with the ISO/IEC Directives, Part 3.

Annexes A, B and C are for information only.

The committee has decided that the contents of this publication will remain unchanged until 2006. At this date, the publication will be

- reconfirmed;
- withdrawn;
- replaced by a revised edition, or
- amended.

440 Introduction

Part 4-44 of IEC 60364 provides rules for the protection against the effects of conducted and radiated disturbances on electrical installations.

The rules of this standard do not apply to systems which are wholly or partly under control of public power supply companies (see scope of IEC 60364-1).

The fault-current flowing in the earth electrode of the exposed-conductive-parts of the sub-station causes a significant rise of the potential of the exposed-conductive-parts of the sub-station to the general mass of the earth, i.e. a fault-voltage, whose magnitude is governed by

- the fault-current magnitude, and
- the resistance of the earth electrode of the exposed-conductive-parts of the sub-station.

The fault-current may cause

- a general rise of the potential of the low-voltage system with respect to earth, i.e. stress-voltages which may cause a breakdown of the insulation in low-voltage equipment,
- a general rise of the potential of the exposed-conductive-parts of the low-voltage system with respect to earth, which may give rise to fault-voltage and touch voltages.

NOTE In this standard, the expression "high-voltage" (HV) refers to voltages exceeding the upper limit of voltage band II. The expression "low-voltage" (LV) refers to voltages not exceeding the upper limit of voltage band II.

Clause 443 is intended to describe the means by which transient overvoltages can be limited to reduce the risk of failures in the installation, and in electrical equipment connected to it, to an acceptable level. This approach is in line with the principles of insulation co-ordination in IEC 60664. IEC 60664-1 requires technical committees to specify an appropriate impulse withstand category (overvoltage category) for their equipment, that means a minimum impulse withstand voltage for the equipment, according to its application and the related impulse withstand categories.

NOTE Following 2.2.2 of IEC 60664-1, technical committees should specify the relevant information. It is recommended to indicate the rated impulse withstand voltage to be supplied with the equipment and the way in which this should be done.

(Introduction IEC 60374-4-444, in part).

In clause 444, basic recommendations are described to mitigate electromagnetic disturbances. Actually electromagnetic interferences (EMI) can disturb or damage information technology systems or equipment, equipment with electronic components or circuits. Currents due to lightning, switching operations, short-circuits and other electromagnetic phenomena can cause overvoltages and electromagnetic interference.

These effects appear

- where large metal loops exist[1]); and
- where different electrical wiring systems are installed on different routes, e.g. for power supply and for signalling information technology equipment within a building.

---

[1]) Equipotential bonding systems, structural metalwork or pipe systems for non-electrical supplies, e.g. for water, gas, heating or air conditioning, can create such induction loops.

The value of the induced voltage depends on the rate of rise (d*i*/d*t*) of the interference current, and on the size of the loop.

Power cables carrying large currents with a high rate of rise of current (d*i*/d*t*) (e.g. the starting current of lifts or currents controlled by rectifiers) can induce overvoltages in cables of information technology systems, which can influence or damage information technology or similar electrical equipment.

In or near rooms for medical use, electric or magnetic fields of electrical installations can interfere with medical electrical equipment.

Clause 445 deals with the precautions to be taken in the case of undervoltages.

ELECTRICAL INSTALLATIONS OF BUILDINGS –

Part 4-44: Protection for safety – Protection against voltage disturbances and electromagnetic disturbances

440.1 (442.1.1) Scope

The rules of this part of IEC 60364 are intended to provide for the safety of persons and equipment in a LV system in the event of a fault between the HV system and earth in the HV part of transformer stations which supply low-voltage systems.

440.2 (442.1.4) Normative references

The following normative documents contain provisions which, through reference in this text, constitute provisions of this part of IEC 60364. For dated references, subsequent amendments to, or revisions of, any of these publications do not apply. However, parties to agreements based on this part of IEC 60364 are encouraged to investigate the possibility of applying the most recent editions of the normative documents indicated below. For undated references, the latest edition of the normative document referred to applies. Members of IEC and ISO maintain registers of currently valid International Standards.

442 Protection of low-voltage installations against temporary overvoltages and faults between high-voltage systems and earth

442.1 General requirements

NOTE The following clauses consider only four situations which generally cause the most severe temporary overvoltages such as defined in IEV 60050(604), definition 604-03-12:

- fault between the high-voltage system(s) and earth. The corresponding subclauses should be read in conjunction with annex A;
- loss of the neutral in a low-voltage TN and TT system (see 442.6);
- accidental earthing of a low-voltage IT system (see 442.7);
- short-circuit in the low-voltage installation (see 442.8).

442.1.2 Fault-voltage

The magnitude and the duration of the fault-voltage or the touch voltage due to an earth-fault in the high-voltage system shall not exceed the values given by curve F and T respectively of figure 44A.

442.1.3 Stress-voltage

The magnitude and the duration of the power-frequency stress voltage of the LV equipment in the consumer's installation due to an earth fault in the high voltage system shall not exceed the values of table 44A.

NOTE 1 The power-frequency stress voltage is the voltage which appears across the insulation.

NOTE 2 A higher stress voltage is permitted for the low-voltage equipment of the sub-station if the insulation level of the equipment is compatible and under the conditions of 442.3.

Table 44A – Permissible stress voltage

Permissible a.c. stress voltage on equipment in low-voltage installations V	Disconnecting time s
U_0 + 250 V	>5
U_0 + 1 200 V	≤5

NOTE 1 In particular cases (e.g. line conductor earthed), where the (highest) nominal voltage of the low-voltage system to earth is not U_0, this voltage shall be specified.

NOTE 2 The first line of the table relates to systems having long disconnection times, for example inductively earthed high-voltage system. The second line relates to systems having short disconnection times, for example solidly earthed high-voltage systems. Both lines together are relevant design criteria for insulation of low-voltage equipment with regard to temporary overvoltage (see 1.3.7.1 of IEC 60664-1).

NOTE 3 Such temporary a.c. overvoltage is also to be expected in basic, double and reinforced insulation of low-voltage equipment used outside the main equipotential bonding and connected to a TN system (whose neutral conductor is earthed in the transformer substation through the protective earth electrode of the high-voltage system). It is not necessary to expect such overvoltage within the area of main equipotential bonding which is connected to the protective conductor of a TN system at the origin of the installation of the building.

442.2 Earthing systems in transformer sub-stations

At the transformer sub-station, there shall be one earthing system to which shall be connected

- earth electrodes,
- the transformer tank,
- metallic coverings of high-voltage cables,
- metallic coverings of low-voltages cables except where the neutral conductor is earthed via a separate earth electrode,
- earth wires of high-voltage systems,
- the exposed-conductive-parts of high-voltage and low-voltage equipment,
- extraneous-conductive-parts.

442.3 Earthing arrangements in transformer sub-stations

The conditions enumerated under 442.4 and 442.5 are deemed to be complied with if one or both of the conditions stated in 442.3.1 or the condition in 442.3.2 is met. Where none of the conditions of 442.3.1 or 442.3.2 is met, the requirements of 442.4 and 442.5 shall be applied.

442.3.1 The transformer sub-stations shall be connected to cables with suitable earthed metallic coverings, whether high-voltage cables, low-voltage cables or a combination of both high- and low-voltage cables.

The total length of these cables shall exceed 1 km.

442.3.2 The earthing resistance of the exposed-conductive-parts of the transformer sub-station does not exceed 1 Ω.

442.4 Earthing arrangements with regard to type of earthing systems in LV installations

442.4.1 Symbols

In the following subclauses, the symbols are

I_m that part of the earth fault current in the high-voltage system that flows through the earth electrode of the exposed-conductive-parts of the transformer sub-station.

R is the resistance of the earth electrode of the exposed-conductive-parts of the transformer sub-station.

U_0 is the line-to-neutral voltage of the low-voltage system.

U is the line-to-line voltage of the low-voltage system.

U_f is the fault-voltage in the LV system between exposed-conductive-parts and earth.

U_1 is the stress-voltage in the LV equipment of the transformer sub-station.

U_2 is the stress-voltage in the LV equipment of the consumer's system.

442.4.2 TN systems

a) When the fault-voltage $R \times I_m$ is disconnected within a time given in figure 44A, the neutral conductor of the LV system may be connected to the earthing electrode of the exposed-conductive-parts of the transformer sub-station (see TN-a in figure 44B).

NOTE If the exposed-conductive-parts of the low-voltage equipment of the consumer's installation within the building are connected to the main equipotential bonding by a protective conductor, the touch voltage will be effectively zero.

b) If the condition under a) is not fulfilled, the neutral conductor of the LV system shall be earthed via an electrically independent earth electrode (see TN-b in figure 44B). In this case, the conditions of 442.5.1 apply.

442.4.3 systems

a) When the relation between the stress-voltage ($R \times I_m + U_0$) and the disconnecting time given in table 44A is complied with for the LV equipment of the consumer's installation, the neutral conductor of the LV system may be connected to the earthing electrode of the exposed-conductive-parts of the transformer sub-station (see TT-a in figure 44C).

b) If the condition under a) is not fulfilled, the neutral conductor of the LV system shall be earthed via an electrically independent earth electrode (see TT-b in figure 44C). In this case, the conditions of 442.5.1 apply.

If the exposed-conductive-parts of the low-voltage equipment of the consumer's installation within the building are connected to the main equipotential bonding by a protective conductor, the touch voltage will be effectively zero.

442.4.4 IT-systems

a) When the fault-voltage $R \times I_m$ is disconnected within a time given in figure 44A, the exposed-conductive-parts of the LV equipment of the consumer's installation may be connected to the earthing electrode of the exposed-conductive-parts of the sub-station (see figures 44D, 44J and 44K).

If this condition is not fulfilled, the exposed-conductive-parts of the LV equipment of the LV installation shall be connected to an earthing system electrically independent from the earthing electrode of the exposed-conductive-parts of the sub-station (see figures 44E to 44H).
