This document is not an ASTM standard and is intended only to provide the user of an ASTM standard an indication of what changes have been made to the previous version. Because it may not be technically possible to adequately depict all changes accurately, ASTM recommends that users consult prior editions as appropriate. In all cases only the current version of the standard as published by ASTM is to be considered the official document.

Designation: E2533 – 17^{ε1} E2533 – 21

Standard Guide for Nondestructive TestingExamination of Polymer Matrix Composites Used in Aerospace Applications¹

This standard is issued under the fixed designation E2533; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

e¹ NOTE—An editorial correction was made to subsection 4.2 in November 2017.

This standard has been approved for use by agencies of the U.S. Department of Defense.

1. Scope

1.1 This guide provides information to help engineers select appropriate nondestructive testing (NDT) methods to characterize aerospace polymer matrix composites (PMCs). This guide does not intend to describe every inspection technology. Rather, emphasis is placed on established NDT methods that have been developed into consensus standards and that are currently used by industry. Specific practices and test methods are not described in detail, but are referenced. The referenced NDT practices and test methods have demonstrated utility in quality assurance of PMCs during process design and optimization, process control, after manufacture inspection, in-service inspection, and health monitoring.

1.2 This guide does not specify accept-reject criteria and is not intended to be used as a means for approving composite materials or components for service.

1.3 This guide covers the following established NDT methods as applied to PMCs: Acoustic Emission (AE, Section 7);); Computed Tomography (CT, Section 8);); Leak Testing (LT, Section 9);); Radiographic Testing, Computed Radiography, Digital Radiography, and Radioscopy (RT, CR, DR, RTR, Section 10);); Shearography ((Section 11);); Strain Measurement (contact methods, (Contact Methods, Section 12);); Thermography ((Section 13);); Ultrasonic Testing (UT, Section 14);); and Visual Testing (VT, Section 15).

1.4 The value of this guide consists of the narrative descriptions of general procedures and significance and use sections for established NDT practices and test methods as applied to PMCs. Additional information is provided about the use of currently active standard documents (an emphasis is placed on applicable standard guides, practices, and test methods of ASTM Committee E07 on Nondestructive Testing), geometry and size considerations, safety and hazards considerations, and information about physical reference standards.

1.5 To ensure proper use of the referenced standard documents, there are recognized NDT specialists that are certified in accordance with industry and company NDT specifications. It is recommended that a NDT specialist be a part of any composite component design, quality assurance, in-service maintenance, or damage examination.

1.6 This guide summarizes the application of NDT procedures to fiber- and fabric-reinforced polymeric matrix composites. The

¹ This guide is under the jurisdiction of ASTM Committee E07 on Nondestructive Testing and is the direct responsibility of Subcommittee E07.10 on Specialized NDT Methods.

Current edition approved June 1, 2017 Feb. 1, 2021. Published June 2017 March 2021. Originally approved in 2009. Last previous edition approved in $\frac{20162017}{2017}$ as E2533E2533 - 17^{ϵ_1} -16a. DOI: $\frac{10.1520}{E2533-17E01.10.1520}$

€2533 – 21

composites of interest are primarily, but not exclusively, limited to those containing high modulus (greater than 20 GPa $(3 \times 10^6 \text{ psi})$) fibers. Furthermore, an emphasis is placed on composites with continuous (versus discontinuous) fiber reinforcement.

1.7 This guide is applicable to PMCs containing, but not limited to, bismaleimide, epoxy, phenolic, poly(amide imide), polybenzimidazole, polyester (thermosetting and thermoplastic), poly(ether ether ketone), poly(ether imide), polyimide (thermosetting and thermoplastic), poly(phenylene sulfide), or polysulfone matrices; and alumina, aramid, boron, carbon, glass, quartz, or silicon carbide fibers.

NOTE 1—Per the discretion of the cognizant engineering organization, composite materials not developed and qualified in accordance with the guidelines in CMH-17, Volumes 1 and 3 should have an approved material usage agreement.

1.8 The composite materials considered herein include uniaxial laminae, cross-ply laminates, angle-ply laminates, and sandwich constructions. The composite components made therefrom include filament-wound pressure vessels, flight control surfaces, and various structural composites.

1.9 For current and potential NDT procedures for finding indications of discontinuities in the composite overwrap <u>and thin-walled</u> <u>metallic liners</u> in filament-wound pressure vessels, also known as composite overwrapped pressure vessels (COPVs), refer to <u>GuideGuides E2981-</u> and E2982, respectively.

1.10 For a summary of the application of destructive ASTM standard practices and test methods (and other supporting standards) to continuous-fiber reinforced PMCs, refer to Guide D4762.

1.11 <u>Units</u>—The values stated in SI units are to be regarded as the standard. The values given in parentheses <u>after SI units</u> are provided for information <u>only.only</u> and are not considered standard.

1.12 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety safety, health, and health environmental practices and determine the applicability of regulatory limitations prior to use.

1.13 This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.

3. Terminology

3.1 *Abbreviations*—The following abbreviations are adopted in this guide: Acoustic Emission (AE), Computed Radiography (CR), Computed Tomography (CT), Digital Radiography (DR), Leak Testing (LT), Radiographic Testing (RT), Radioscopy (RTR), and Ultrasonic Testing (UT).

ASTM E2533-21

3.2 *Definitions*—Definitions of terms related to NDT of aerospace composites which appear in Terminology E1316 and Terminology D3878 shallshould apply to the terms used in thethis guide.

3.3 Definitions of Terms Specific to This Standard:

3.3.1 *aerospace*<u>aerospace</u>, <u>n</u>any component that will be installed on a system that flies.

3.3.2 *cognizant engineering organization*—<u>organization</u>, <u>n</u>—the company, government agency, or other authority responsible for the design, or end use, of the system or component for which NDT is required. This, in addition to the design personnel, may include personnel from engineering, materials and process engineering, stress analysis, NDT, or quality groups and other, as appropriate.

3.3.2.1 Discussion—

This, in addition to the design personnel, may include personnel from engineering, materials and process engineering, stress analysis, NDT, or quality groups and other, as appropriate.

E2533 - 21

3.3.3 *composite material_material, n_*see Terminology D3878.

3.3.4 *composite <u>component</u> <u>component</u>, <u>n</u> a finished part containing composite material(s) that is in its end use application configuration, and which has undergone processing, fabrication, and assembly to the extent specified by the drawing, purchase order, or contract.*

3.3.5 *disbond*—*disbond*, *n*—see Terminology D3878.

3.3.6 *in-service*—*in-service*, *n*—refers to composite components that have completed initial fabrication and are in use (or in storage) for their intended function.

3.3.7 *microcrack*, *microcrack*, *n*—invisible cracks (< 50 to 100 µm size) that are precursors to visible cracks.—In angle-ply continuous fiber-reinforced composites, for example, microcracks form preferentially under tensile loading in the matrix in off-axis plies. Since most microcracks do not penetrate the reinforcing fibers, microcracks in a cross-plied tape laminate or in a laminate made from cloth prepreg are usually limited to the thickness of a single ply.

3.3.7.1 Discussion—

In angle-ply continuous fiber-reinforced composites, for example, microcracks form preferentially under tensile loading in the matrix in off-axis plies. Since most microcracks do not penetrate the reinforcing fibers, microcracks in a cross-plied tape laminate or in a laminate made from cloth prepreg are usually limited to the thickness of a single ply.

3.3.8 *reference standards—standards, n*_objects that provide a known, reproducible, and repeatable response to a specific stimulus. Maystimulus; may be in the form of hardware or software.

3.3.9 sandwich construction construction, n-see Terminology D3878.

4. Summary of Guide

4.1 This guide describes and provides references for the practice and utilization of the following established NDT procedures as applied to polymeric matrix composites:

4.1.1 Acoustic Emission (Section 7).

ASTM E2533-21

https://standards.iteh.al/catalog/standards/sist/8a85dd82-91d8-4673-bad5-e17e83177de1/astm-e2533-21 4.1.2 Computed Tomography (X-ray Method) (Section 8).

4.1.3 Leak Testing (Section 9).

4.1.4 Radiography, Computed Radiography, Digital Radiography with Digital Detector Array Systems, and Radioscopy (Section 10).

4.1.5 Shearography (Section 11).

4.1.6 Strain Measurement (Strain Gauges) (Section 12).

4.1.7 Infrared Thermography (Non-Contact Methods Using Infrared Camera) (Section 13).

4.1.8 Ultrasonic Testing (Section 14).

4.1.9 Visual Testing (Section 15).

4.2 *NDT Method Selection*—Composite components such as laminates, moldings, and subassemblies may be inspected by simple procedures consisting of dimensional and tolerance measurements, weight and density determinations, cure determinations by hardness measurements, visual testing for defects, and tapping for void determinations. If the integrity of the subassembly warrants a more complete inspection, this can be accomplished by using various NDT procedures discussed in this guide. Nondestructive tests can usually be made rapidly. However, nondestructive testing will, in general, add to component cost and should be used only when warranted on critical applications. Also, the extent of NDT on composite parts depends on whether the part is a primary

E2533 – 21

structure safety of flight part, or secondary structure non-safety of flight part. The type or class of part is usually defined on the engineering drawing. Some of the flaws that can be detected by NDT are given in Table 1.

4.3 Other critical defect characteristics not mentioned in Table 1 that need to be considered when establishing NDE procedures include defect size, defect shape, defect depth, defect orientation, fiber volume fraction, resin rich regions, resin poor regions, cure state, fiber sizing, fiber-matrix bonding, crazing (cracking of amorphous matrix resins due to exposure to stress or the service environment), residual and internal stress, degradation (chemical and physical attack), and impact damage.

4.4 *General-Facility and Personnel-Qualification*—Minimum general requirements for NDT facilities and personnel qualification are given in PracticeSpecification E543. This practicespecification can be used as a basis to evaluate testing or inspection agencies, or both, and is intended for use for the qualifying or accrediting, or both, of testing or inspection agencies, public or private.

4.5 *Personnel Certification*—NDT personnel should be certified in accordance with a nationally or internationally recognized practice or standard such as ANSI/ASNT-CP-189, SNT-TC-1A, NAS 410, ISO 9712, or a similar document. The practice or standard used and its applicable revisions should be specified in any contractual agreement between the using parties.

<u>4.6 Personnel Qualification</u>—NDT personnel should be qualified by accepted training programs, applicable on-the-job training, or a competent mentor or component manufacturer. Personnel will be only qualified to inspect parts that come under direct training experience or production.

4.7 General Equipment and Instrumentation Considerations—General equipment and instrumentation considerations are provided in PracticeSpecification E543. NDT method specific considerations are discussed in the appropriate section of this guide (Sections 77 - 15 - to - 15).

iTeh Standards

4.8 *Reference Standards*—Physical reference standards simulating target imperfections or discontinuities are used to validate NDT results. The use of physical reference standards also helps to ensure reproducibility and repeatability of measurements. Certified physical reference standards calibrated by accepted government or industrial agencies may be used.

4.9 *Extent of Examination*—Specific applications may require local regions or the entire component to be examined. Examination may be real time or delayed based upon the availability of data. Examination may be direct, or indirect, on site or remote as specified in the contractual agreement or established requirements documents.

https://standards.iteh.ai/catalog/sta TABLE 1 Flaws Detected By NDT Procedures 5-e17e83177de1/astm-e2533-21

^A Can detect after impact (voids).

^B Depends on opening/size of crack.

^C Depends on angle of beam relative to planar defect and opening.

^D Only in central projection (Radiography, CR).

^E Radioscopic mode (Radiography with DDA).

^F For Radiography, applicable to CR and digitized films only.

4.10 *Timing of Examination*—Examinations shallshould be performed in accordance with the contractual agreement or established requirements documents, and may be performed during the life cycle of the article under test.

4.11 *Type of Examinations*—Many different NDT system configurations are possible due to the wide range of system components available. It is important for the purchaser of NDT to understand the capability and limitations of the applicable configuration. Selection of the NDT procedure and system shallshould be at the discretion of the testing agency unless specified by the purchaser in a contract or requirements document (that is, engineering drawing, specifications, etc.).

4.12 A tabular comparison of most of the established NDT procedures discussed in the guide is given in Appendix X1 of <u>PracticeSpecification E543</u>; namely, acoustic emission, leak testing, radiography, strain measurement, thermography (infrared), and ultrasound are covered. The comparison summarizes properties sensed or measured, typical discontinuities detected, representative application, applicable ASTM standards, and advantages and limitations. A similar overview is provided in Table 2.

5. Significance and Use

5.1 This guide references requirements that are intended to control the quality of NDT data. The purpose of this guide, therefore, is not to establish acceptance criteria and therefore approve composite materials or components for aerospace service.

5.2 Following the discretion of the cognizant engineering organization, NDT for fracture control of composite and bonded materials should follow additional guidance described in MIL-HDBK-6870, NASA-STD-(I)-5019, or MSFC-RQMT-3479, or a combination thereof, as appropriate (not covered in this guide).

5.3 Certain procedures referenced in thethis guide are written so they can be specified on the engineering drawing, specification, purchase order, or contract, for example, Practice E1742E1742/E1742M (Radiography).

5.4 Acceptance Criteria—Determination about whether a composite material or component meets acceptance criteria and is suitable for aerospace service <u>mustshould</u> be made by the cognizant engineering organization. When examinations are performed in accordance with the referenced documents in this guide, the engineering drawing, specification, purchase order, or contract <u>shallshould</u> indicate the acceptance criteria.

5.4.1 Accept/reject criteria shallshould consist of a listing of the expected kinds of imperfections and the rejection level for each.

5.4.2 The classification of the articles under test into zones for various accept/reject criteria shallshould be determined from contractual documents.

5.4.3 *Rejection of Composite Articles*—If the type, size, or quantities of defects are found to be outside the allowable limits specified by the drawing, purchase order, or contract, the composite article shallshould be separated from acceptable articles, appropriately identified as discrepant, and submitted for material review by the cognizant engineering organization, and dispositioned as (1) acceptable as is, (2) subject to further rework or repair to make the materials or component acceptable, or (3) scrapped when required by contractual documents.

5.4.4 Acceptance criteria and interpretation of result shallshould be defined in requirements documents prior to performing the examination. Advance agreement should be reached between the purchaser and supplier regarding the interpretation of the results of the examinations. All discontinuities having signals that exceed the rejection level as defined by the process requirements documents shallshould be rejected unless it is determined from the part drawing that the rejectable discontinuities will not remain in the finished part.

5.5 *Life Cycle Considerations*—The referenced NDT practices and test methods have demonstrated utility in quality assurance of PMCs during the life cycle of the product. The modern NDT paradigm that has evolved and matured over the last twenty–five years has been fully demonstrated to provide benefits from the application of NDT during: (*a*) product and process design and optimization, (*b*) on-line process control, (*c*) after manufacture inspection, (*d*) in-service inspection, and (*e*) health monitoring.

5.5.1 In-process NDT can be used for feedback process control since all tests are based upon measurements which do not damage the article under test.

TABLE 2 General Overview of Established NDT Procedures

NDT Method	Applications	Advantages	Limitations	What Is Seen and Reported?	Other Considerations
Acoustic Emission	Global monitoring of composite structures to detect and locate active sources in real time.	Remote and continuous monitoring on an entire composite article in real time is possible. Can also detect growth of active imperfections or discontinuities, and detect and determine the location of discontinuities and defects that may be inaccessible by other NDT procedures.	The part being inspected must be stressed by mechanical, load, pressure, temperature, or other stimulus. With the exception of certain imperfections or discontinuities that AE detects by friction- generated AE (for example, delamination surfaces rubbing), AE- inactive (non- propagating) imperfections or discontinuities cannot be detected and structurally insignificant imperfections or discontinuities may produce AE. Therefore, the significance of a detected AE source cannot be assessed unambiguously.	The AE technique records transient elastic waves produced by applied stress or resulting stress relaxation of the composite material or component. The mechanical waves are produced as either burst or continuous AE. AE activity, intensity and severity correlated with applied stress yield information on the degradation within the article under test.	Inspection tests and results are unique to each application and should be conducted with expert oversight.
Computed Tomography	Detects sub-surface volumetric imperfections or discontinuities. Provides quantitative, volumetric analysis of imperfections or discontinuities detectable by other NDT procedures. Also suitable for measuring geometric ebaracteristics	Produces clear cross- sectional image slices of an object. Obtains 3D imperfection or discontinuity data. Extensive image processing capability.	Requires access to all sides of the article under test. Not very applicable to the inspection of large areas, or objects with high (>15) aspect ratios.	A digitized cross- sectional CT density map (tomogram) of the article under test. Allows full, three dimensional CT- density maps to be obtained for sufficiently small composite parts.	Tooling and/or part- handling fixtures may be required.

	discontinuities detectable by other NDT procedures. Also suitable for measuring geometric characteristics.	processing capability.	aspect ratios.	obtained for sufficiently small composite parts.	
Leak Testing	Any composite material or component across which a differential pressure exists and where through-leakage or in-leakage of product, air, water vapor, or other contaminant over the projected service life are of concern.	Less ambiguous than liquid penetrant testing; more sensitive than AE or UT.	Test equipment costs increase as the required leak test sensitivity increases.	Qualitative indications, for example bubbles, or quantitative measurements, for example, detector deflections, that ascertain the presence or location, or concentration or leak rate of a leaking fluid.	Different techniques are available for characterization of large leaks (with rates as high as 10^{-2} Pa m ³ s ⁻¹ (10^{-1} std cm ³ s ⁻¹)) and small leaks (rates less than 10^{-5} Pa m ³ s ⁻¹ (10^{-4} std cm ³ s ⁻¹)).

5.5.2 The applicability of NDT procedures to evaluate PMC materials and components during their life cycle is summarized in Tables 3 and 4.

5.6 *General Geometry and Size Considerations*—Part contour, curvature, and surface condition may limit the ability of certain tests to detect imperfections with the desired accuracy.

5.7 *Reporting*—Reports and records shallshould be specified by agreement between purchaser and supplier. It is recommended that any NDT report or archival record contain information, when available, about the material type;type; method of fabrication;

TABLE 2 Continued

NDT Method	Applications	Advantages	Limitations	What Is Seen and Reported?	Other Considerations
Radiography, Computed Radiography, Radiography with Digital Detector Arrays, Radioscopy	Primarily detects sub- surface imperfections or discontinuities such as porosity & inclusions. Planar imperfections or discontinuities are detected if the beam is directed along the imperfection or discontinuity and the unsharpness is less than the imperfection or discontinuity opening/ size.	Film and some imaging plates can be cut and placed almost anywhere on the part. Digital images can be processed for additional information and automated defect recognition. In radioscopy, techniques using an image intensifier and DDA can be automated by interfacing with a robot or part manipulator thus allowing the potential for a faster inspection.	Requires access to both sides of the article under test. Accessibility may need to be evaluated. Unable to determine depth of imperfections or discontinuities; sometimes possible from digital images after calibration or with additional X-ray exposures from different directions.	Projected area and density variation of subsurface imperfections or discontinuities.	Part may need to be moved to an X-ray lab; Film RT requires film storage and disposal of chemicals which can be expensive. Digital techniques (CR, DDA) are usually faster. Radiation safety. In radioscopy, radiation safety more problematic if a moving source is used, versus movement of part.
Shearography	Detects subsurface imperfections or discontinuities or changes in modulus or out of plane deformation.	Well suited for high speed, automated inspection in production environments:	Subsurface imperfection or discontinuity must be sufficiently large to cause measurable surface deformation under load. Surface condition, especially glossiness, can interfere with accurate shearographic detection, thus requiring the use of surface dulling agents (exception: thermal shearography).	An interference pattern created by subtracting or superimposing images of the article under test taken before and after loading, thus revealing localized strain concentrations.	Additional equipment is required to determine surface derivative slope changes, and thus uses the method as a quantitative tool.

Additional equipment is required to determine surface derivative slope changes, and thus uses the method as a quantitative tool.
Strain Measurement	Can be used to measure static and dynamic tensile and compressive strain, as well as shearing, Poisson, bending, and torsional strains.	Relatively inexpensive, and less bulky and better resolution than extensometers (can achieve an overall accuracy of better than ± 0.10% strain).	Individual strain gauges cannot be calibrated and are susceptible to unwanted noise and other sources of error such as expansion or contraction of the strain- gauge element, change in the resistivity, and hysteresis and creep caused by imperfect bonding.	The output of a resistance measuring circuit is expressed in millivolts output per volt input.	Depending on desired sensitivity, resistance to drift, insensitivity to temperature variations, or stability of installation, a variety of strain gauges are available (for example, semiconductor wafer sensors, metallic bonded strain gauges, thin-film and diffused semiconductor strain gauges).

manufacturers name, part number, lot, <u>fabrication</u>; manufacturer's name; part number; lot; date of lay-up <u>and/oror</u> of cure, <u>or both</u>; date and pressure load of previous tests (for pressure <u>vessels</u>), <u>vessels</u>); and previous service history (for in-service and failed composite articles). Forwards and backwards compatibility of data, data availability, criticality (length of data retention), specification change, specification revision and date, software and hardware considerations will also govern how reporting is performed.

6. Procedure

6.1 When NDT produces an indication of a material discontinuity, the indication is subject to interpretation as false, nonrelevant,

Thermography	Detects disbonds, delaminations, voids, pits, cracks, inclusions, and occlusions, especially in thin articles under test having low thermal conductivity, low reflectivity/high emissivity surfaces, and in materials which dissipate energy efficiently,	Quick observation of large surfaces and identification of regions that should be examined more carefully.	Composites have temperature limits beyond which irreversible matrix and fiber damage can occur. Imperfection or discontinuity detection depends on orientation of an imperfection or discontinuity relative to the direction of heat flow. In thicker materials, only qualitative indications of imperfections or discontinuities are possible.	The areal temperature distribution is measured by mapping contours of equal temperature (isotherms), thus yielding a heat emission pattern related to surface and subsurface defects.	Both contact (requires application of a coating) and noncontact methods (relies on detection of infrared blackbody radiation) are available. Thermography is either passive or active, active thermography can be further subdivided into pulse or lock-in techniques.

or relevant (Fig. 1). If the indication has been interpreted as relevant, the necessary subsequent evaluation will result in the decision to accept or reject the composite material or component.

7. Acoustic Emission

7.1 Referenced Documents

7.1.1 ASTM Standards:² E569 Practice for Acoustic Emission Monitoring of Structures during Controlled Simulation

TABLE 3 Application Examples of Established NDT Procedures During Life Cycle

NDT Method	Application
Acoustic Emission	May be used for quality control of production and fabrication processes (for example, to evaluate adhesive bonding after lay-up winding or curing), for proof-testing of pressure vessels after fabrication, and for periodic in-service and health monitoring inspections prior to failure.
Computed Tomography	May be used as a post-fabrication metrological method to verify engineering tolerances.
Leak Testing	May be used to validate leak tightness following fabrication, and in-service re-qualification of pressure vessels. For example, helium leak detection can be used during composite article fabrication to detect and seal leaks permanently (preferable) or temporarily in such a manner to allow repair at a later time. Similarly, halogen gas leak detection has been used in production examination.
Radiography and Radioscopy	May be used during fabrication inspection to evaluate honeycomb core imperfections or discontinuities such as node bonds, core-to-core splices, core-to-structure splices, porosity, included material as well as verification of structural placement.
Shearography	May be used in quality assurance, material optimization, and manufacturing process control.
Strain Measurement	May be used during proof testing before placement into service, or during periodic re-qualification. Can be destructive depending on the strain thresholds reached during test.
Thermography	May be used to follow imperfection or discontinuity growth during service. If video thermographic equipment is used, systems that are being dynamically tested or used can be examined in real-time.
Ultrasonic Testing	Automatic recording systems allow parts to be removed from a processing line when defect severity exceeds established limits. Measurement of the apparent attenuation in composite materials is useful in applications such as comparison of crystallinity and fiber loading in different lots, or the assessment of environmental degradation. The most common method is applied for laminar oriented defect detection such as impact damage causing delamination fiber fracturing, included material, and porosity.
Visual Testing	Used primarily for quality inspections of composite materials and components upon receipt (after fabrication and before installation).

FIG. 1 Consequences of Detecting a Material Discontinuity (Indication) by NDT

7.1 General Procedure

iTeh Standards

7.1.1 Specially designed sensors (transducers) are used to detect transient elastic stress waves (AE) in a material produced as a result of applied stress (tension, compression, torsion, internal pressure, or thermal). The sensors are coupled to the article under test with a suitable couplant (for example, grease), or by means of an epoxy cement or other adhesive. The output from the sensor is amplified and filtered to eliminate unwanted frequencies. The conditioned AE signal is then digitized and segmented into discrete AE waveform packets through a process of threshold detection. Digital signal processing converts the transient waveform packets into extracted time and frequency features which describe the transient waveform's shape, size, and frequency content. In sophisticated approaches, these features are sometimes analyzed together using artificial intelligence, pattern recognition and/orrecognition, or neural network techniques techniques, or a combination thereof, to distinguish true AE sources from noise. When multiple sensors in an array detect the same AE transient, location determination can be accomplished using arrival time analysis (triangulation) techniques. When multiple events are located close together they form an event cluster indicating continuing activity which is indicative of an active growing source. In addition to AE activity generated by growing imperfections or discontinuities, activity can also originate from preexisting imperfections or discontinuities that are not growing (for example, delamination surfaces rubbing together during depressurization of a pressure vessel).

7.2 Significance and Use

7.2.1 Acoustic emission is a term used to describe transient elastic stress waves produced in solids as a result of the application of stress. The applied stress may include mechanical forces (tension, compression or torsion), internal pressure, or thermal gradients (can often be accomplished by use of a hot-air gun). The applied stress may be short to long, random, or cyclic. The applied stress may be controlled by the examiner, or may already exist as part of the process. In either case, the applied stress is measured along with the AE activity.

7.2.2 The resulting AE stress waves are produced by the rapid release of energy within the material from a localized source. The AE signal from composites often consists of both continuous AE (qualitative description of a sustained signal level produced by rapidly occurring AE events) and burst AE (qualitative description of discrete signals of varying duration that are usually of higher amplitude than continuous AE).

7.2.3 The AE technique records transient elastic stress waves produced by applied stress or resulting stress relaxation of the composite material or component. The stress waves are produced as either burst or continuous AE. AE activity, intensity, and severity correlated with applied stress yield information on the degradation within the article under test. Lack of AE activity is an indication of a sound structure, while more activity is an indication that the structure is degraded. The source is located by triangulation or zone location methods.

TABLE 5 Summary of Acoustic Emission

Applications	How It Works	Advantages	Limitations	What Is Seen and Reported?
Global monitoring of composite structures to detect and locate active sources. Evaluation of the structural integrity of finished composite components such as pipes, tubes, tanks, and pressure vessels: Quality control of production and fabrication processes (for example, during lay up winding, or curing): Proof testing after fabrication. Also can be used as an alternative method to periodic hydrostatic proof testing: Periodic monitoring of regions of interest or concern during service. Continuous, real time monitoring of structures (health monitoring). Evaluation of adhesive bonding: 	AE transducers are coupled to the article under test to detect transient elastic stress waves (or AE) produced during application of stress (mechanical, thermal or pressure). The location of the source is located by triangulation or area (zonal) location methods:	Remote and continuous monitoring of the entire article under test in real time is possible. Can detect growing of active imperfections or discontinuities. Can detect discontinuities and defects that may be inaccessible to other NDT procedures, and determine their location. Can be used for proof testing of new or in-service components. Can be used for periodic or continuous (in situ) health monitoring:	The part or article under test must be stressed by mechanical load, pressure, or temperature, or other stimulus. Imactive (nonpropagating) imperfections or discontinuities cannot be detected and structurally insignificant imperfections or discontinuities may produce AE. Therefore, the significance of a detected AE source cannot be assessed unambiguously. Monrelevant noise must be placed on the part or article under test. Transducers must be placed imperfections or discontinuities. Umatter of the part or article under test. Umatter of the parter of the part or article under test.	The AE technique monitors transient elastic stress waves generated by various local processes that occur in a short time period in a structure under stress. The lack of sensed AE signals can be an indication of a composite structure having structural integrity Alternatively, if increasing AE activity is detected, that can be an indication of damage occurring in the structure and of a potential loss of structural integrity. The AE signal from composites often consists of both continuous AE (qualitative description of a sustained signal level produced by rapidly occurring AE events) and burst AE (qualitative description of discrete signals of varying duration that are usually of higher amplitude than continuous AE).

ASTM E2533-21

https://standards.iteh.ai/catalog/standards/sist/8a85dd82-91d8-4673-bad5-e17e83177de1/astm-e2533-21

7.2.4 In fiber-reinforced composites, AE is generated by release of stored elastic energy during processes such as cracking of the matrix, or fracture or splitting of fibers. Irreversible viscoelastic processes such as crazing of amorphous matrices or plastic (irreversible) deformation of either the matrix or fiber are not detectable under normal measurement conditions with commercial AE systems.

7.2.5 Interfacial sources of AE in fiber-reinforced composites include debonding of the matrix from the fibers, subsequent fiber pull-out (rubbing), and interlaminar debonding.

7.2.6 AE can also be produced by other acoustic sources in the composite not directly related to the matrix or fiber. These sources include leakage of gas or liquid through a crack, orifice, seal break, or other opening (for example, in composite-overwrapped pressure vessels); and by movement or loosening of parts (thread failure in assembled composite piping systems, for example).

7.2.7 Most AE signals that are useful in NDT have frequencies that are above the audible range. Ordinarily they are between 20 kHz and 1 MHz, depending on application. The rate and amplitude of acoustic emission signals are noted and correlated to structure or composite article characteristics. Lower and higher frequencies are filtered out to avoid interferences from unwanted sources of noise such as machine vibrations or electrical equipment generated noise.

NOTE 2—When detecting leaks using low frequencies generally lower than 100 kHz, it is possible for the leak to excite mechanical resonances within the article under test that may enhance the acoustic signal used to detect leakage.

7.2.8 In addition to immediate evaluation of the emissions detected during application of the stimulus, a permanent record of the number and location of emitting sources and the relative amount of AE detected from each source provides a basis for comparison with sources detected during the examination and during subsequent stimulation.

TABLE 5 Summary of Acoustic Emission

<u>ASTM E2533-21</u>

https://standards.iteh.ai/catalog/standards/sist/8a85dd82-91d8-4673-bad5-e17e83177de1/astm-e2533-21

7.2.9 The basic functions of an AE monitoring system are to detect, locate, and possibly classify emission sources. Other NDT procedures (for example, visual testing, ultrasonic testing, and eddy current testing) should be used to further evaluate the damage detected in an AE-located region.

NOTE 3—Determining the significance of damage with respect to residual strength or remaining life in a composite sample is presently not possible at the same level as is done with a crack in a metallic sample, for example, where facture mechanics can be used to determine the significance of damage.

7.2.10 *Felicity Ratio*—The Felicity ratio is the numerical value of the applied stress at which "significant AE" begins divided by the applied stress during the previous cycle. The term "significant AE" has no quantitative definition at this time, and is open to interpretation by the AE practitioner. However, Practice E1067E1067/E1067M suggests three guidelines for determining the onset of significant AE:

7.2.10.1 More than 5 bursts during a 10 % increase in applied stress.

7.2.10.2 More than 20 counts during a 10 % increase in applied stress.

7.2.10.3 Increasing AE at constant applied stress.

7.2.11 *Effect of Variables on the Felicity Ratio*—Rate of application and removal of stress, time at peak applied stress, AE system sensitivity, time between load cycles, stress state during loading, AE source mechanism, test environment, and the applied stress relative to the ultimate strength of the article under test (stress ratio) can all affect the Felicity ratio. Composite materials and components which have rate dependent properties, such as fiber-reinforced composites with plastic matrices, will be affected to a greater extent.
