Reference number ISO 4871:1996(E)

Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting VIEW a vote.

International Standard ISO 4871 was prepared by Technical Committee ISO/TC 43, *Acoustics*, Subcommittee SC 1, *Noise*.

This second edition cancels and replaces the first edition (ISO 4871:1996) (ISO 4871:1984), which has been technically revised as 249eb760/iso-4871-1996

Annexes A, B, C and D of this International Standard are for information only.

Introduction

© ISO

Information on the acoustic noise emitted by machinery and equipment is needed by users, planners, manufacturers and authorities. This information is required for comparing the noise emitted by different products, for assessing noise emissions against noise limits, for planning workplace noise levels, as well as for checking noise reduction achievements, and may be used for estimating requirements for workplace noise immission.

In order for machinery noise emission data to be useful, uniform methods of measurement and declaration are necessary to achieve the following purposes.

a) Measurement of noise emission

iTeh STATE ISO 3740 series specifies methods for determining the sound power levels of noise sources from sound pressure level measuresound power levels of noise specifies methods for determining the sound power levels from sound intensity level measurements; the ISO 11200 series describes methods for determining emission sound pressure levels at specified positions in the vicinity of machinery and https://standards.iteh.ai/cequipment. Many other standards give test codes for the measured3 ment of the noise emissions of individual types of machinery which are based on these methods.

b) Determination of the noise emission value to be declared

The ISO 7574 series gives methods for determining declared noise emission values which are based primarily on the sound power levels of noise sources. For a complete presentation of declared noise emission values, it is necessary to state the sound pressure levels at specified positions as well as the sound power level. Because of the possible confusion in terminology with respect to sound pressure levels used to define noise immission, the term "emission sound pressure level" is used in this International Standard.

c) Presentation of declared noise emission values

It is of prime importance to declare sound power levels. It is recognized, however, that information on emission sound pressure levels is sometimes required. It is recommended, therefore, that both kinds of quantity be declared, unless otherwise specified. Noise emission declarations can take the form of either a single-number or dualnumber presentation; the choice is made in the noise test code appropriate to the particular family.

d) Verification of declared noise emission values

The ISO 7574 series gives procedures for the verification of a declared noise emission value. In that International Standard, the procedures are applied to verification of declared sound power levels. The procedures of this International Standard are applied to the verification of

both sound power levels and emission sound pressure levels. The information in this International Standard on the verification of declared noise emission values may be used both by a buyer of equipment to compare the relative noise levels of various products, and by a manufacturer as part of a statistical quality control programme.

Requirements on the declaration of noise emission values are given in clause 4.

As the declaration of noise emission of machinery and equipment is the responsibility solely of the manufacturer or supplier, guidelines concerning the declaration are found in annex A.

Requirements on the presentation of declared noise emission values are given in clause 5 and annex B, and those on verification are given in clause 6 and annex C.

Acoustics — Declaration and verification of noise emission values of machinery and equipment

1 Scope

Guidelines for determining declared noise emission values are given in annex A.

This International Standard

- gives information on the declaration of noise emission values,
- describes acoustical and product information to be RD through reference in this text, constitute provisions presented in technical documents for the purposes of noise emission declaration, and near of this international Standard. At the time of publication, the editions indicated were valid. All standards
- are subject to revision, and parties to agreements — specifies a method for verifying the noise emission 71:1996 based on this International Standard are encouraged declaration. https://standards.iteh.ai/catalog/standards/sistt@investigate-the_possibility of applying the most re-

It is applicable to machinery and equipment.

The values to be used for the purposes of noise emission declaration are either declared singlenumber noise emission values, L_d , or declared dualnumber noise emission values, L and K. L is a noise emission value determined directly from measurements and K is the uncertainty associated with those measurements. L_d is the sum of L and K and represents an upper limit which values from repeated measurements are unlikely to exceed at a given confidence level; L_d corresponds to the stated or labelled value, L_{cr} , defined in ISO 7574-1.

The two forms of noise declaration are alternative means of representing any or all of the A-weighted sound power level, L_{WA} , the A-weighted emission sound pressure level at specified positions, L_{pA} , and the C-weighted peak emission sound pressure level at specified positions, $L_{pC,peak}$. The choice as to which of the two forms is used in a particular case depends upon the requirements to be fulfilled. This selection is made, and guidance on the values of *K* is given, in the appropriate noise test code.

Definitions 3

For the purposes of this International Standard, the following definitions apply.

3.1 machinery and equipment: An assembly of linked parts or components with the appropriate actuators control and power circuits, etc., joined to-(standar gether for a specific application. Also included in this

> **3.2 family of machinery or equipment:** Machinery or equipment of similar design or type, intended to perform the same functions.

> **3.3 batch (lot) of equipment:** A number of units of machinery or equipment of the same family produced in quantity, manufactured to the same technical specifications and characterized by the same declared noise emission values.

> NOTE 1 The batch may be either an entire production series or a portion thereof.

> 3.4 operating mode: A condition in which the machinery or equipment is performing its intended function for the purpose of determining its noise emission values.

> 3.5 emission: Airborne sound radiated by a welldefined noise source (e.g. the machine under test) under specified operating and mounting conditions.

> NOTE 2 Emission values may be incorporated in a product label and/or product specification. The basic noise emission quantities are the sound power level of the source itself and the emission sound pressure levels at a work

station and/or at other specified positions (if any) in the vicinity of the source.

3.6 emission sound pressure, *p*: The sound pressure, at a specified position near a noise source, when the source is in operation under specified operating and mounting conditions on a reflecting plane surface, excluding the effects of background noise and of reflections other than those from the plane or planes permitted for the purpose of the test. It is expressed in pascals.

3.7 emission sound pressure level, L_p : Ten times the logarithm to base 10 of the ratio of the square of the emission sound pressure, $p^2(t)$, to the square of the reference sound pressure, p_0^2 , measured with a particular time weighting and a particular frequency weighting, selected from those defined in IEC 651. It is expressed in decibels. The reference sound pressure is 20 µPa.

NOTES

3 Examples include:

NOTES

5 In general, the subscripts "eq" and "T" are omitted since time-averaged emission sound pressure levels are necessarily determined over a certain measurement time interval.

6 Equation (1) is identical to that for the familiar ISO environmental noise descriptor "equivalent continuous sound pressure level" defined in ISO 1996-1. However, the emission quantity defined above is used to characterize the noise emitted by a machine under test and assumes that standardized measurement and operating conditions as well as a controlled acoustical environment are used for the measurements.

3.9 sound power, W: The rate per unit time at which airborne sound energy is radiated by a source. It is expressed in watts.

3.10 sound power level, L_W: Ten times the logarithm to the base 10 of the ratio of the sound power radiated by the source under test to the reference sound power. It is expressed in decibels.

The frequency weighting or the width of the freiTeh STANDARI quency band used shall be indicated. The reference sound power is 1 pW (10^{-12} W). maximum A-weighted emission sound pressure level with time weighting F: L_{pAEmax} ; ten.ar (standards

NOTE 7 For example, the A-weighted sound power level – C-weighted peak emission sound pressure level, is L_{WA}.

L_{pC,peak}. :3805-4815-4b85-9et https://standards.iteh.ai/catalog/standards/sis

4 The single-event emission sound pressure 21evel 769/iso-48 sometimes used and is defined in ISO 11201 to ISO 11204.

The emission sound pressure level shall be determined at a specified position and in accordance with either a test code for a specific family of machines or, if no code exists, a method that complies with the ISO 11200 series.

3.8 time-averaged emission sound pressure level, L_{peqT}: Emission sound pressure level of a continuous steady sound that, within a measurement time interval, T, has the same mean square sound pressure as a sound under consideration which varies with time. It is expressed in decibels.

It is given by the following equation:

$$L_{peqT} = 10 \text{ lg } \frac{1}{T} \int_{0}^{T} \frac{p^{2}(t)}{p_{0}^{2}} dt dB \dots \dots (1)$$

A-weighted time-averaged emission sound pressure levels are denoted by L_{pAeqT} , which is usually abbreviated to L_{pA} . L_{pAeqT} shall be measured with an instrument which complies with the requirements of IEC 804.

3.1,1 noise emission value: A general term by which any one or more of the A-weighted sound power level, L_{WA} , or the A-weighted time-averaged emission sound pressure level, L_{pA} , or the C-weighted peak emission sound pressure level, LpC,peak, is inferred.

3.12 measured noise emission value, L: The Aweighted sound power level, or the A-weighted time-averaged emission sound pressure level, or the C-weighted peak emission sound pressure level, as determined from measurements. Measured values may be determined either from a single machine or from the average of a number of machines, and are not rounded.

3.13 noise emission declaration: Information on the noise emitted by the machine, given by the manufacturer or supplier in technical documents or other literature concerning noise emission values. The noise emission declaration may take the form of either the declared single-number noise emission value or the declared dual-number noise emission value.

3.14 uncertainty, K: Value of the measurement uncertainty associated with a measured noise emission value. It is expressed in decibels.

NOTE 8 Guidance on appropriate values for K is given in annex A.

3.15 declared single-number noise emission value, Ld: The sum of a measured noise emission value and the associated uncertainty, rounded to the nearest decibel:

$$L_{d} = L + K$$

ISO 9296 requires that the declared A-weighted NOTE 9 sound power level, L_{WAd}, of computers and business equipment be expressed in bels using the identity 1 B = 10 dB, rounded to the nearest 0,1 B.

3.16 declared dual-number noise emission value. L and K: A measured noise emission value, L, and its associated uncertainty K_i , both rounded to the nearest decibel.

NOTE 10 If a specific noise test code requires that the mean emission sound pressure level from a number of specified positions be declared, it is denoted by L_{pAm} .

3.17 work station; operator's position: A position in the vicinity of the machine under test which is in- DA env and equipment which is concluse batches of equipment from this family.

application of the same noise emission measurement method on the same noise source at different times and under different conditions (different laboratory, different operator, different apparatus). The standard deviation of reproducibility, therefore, includes the standard deviation of repeatability.

3.22 standard deviation of production, $\sigma_{\rm P}$: Standard deviation of noise emission values obtained on different equipment from a batch of the same family, using the same noise emission measurement method under repeatability conditions (same laboratory, same operator, same apparatus).

3.23 total standard deviation σ_t : Square root of the sum of the squares of the standard deviation of reproducibility and the standard deviation of production:

$$\sigma_{\rm t} = \sqrt{\sigma_{\rm R}^2 + \sigma_{\rm P}^2}$$

3.24 reference standard deviation, σ_{M} : A total standard deviation specified for the family of machinery and equipment, which is considered typical for

(standards, itch ai) NOTE 13 The use of a fixed value for σ_M for each family **3.18 operator:** An individual whose work station is enables the application of a statistical method to deal with in the vicinity of a machine and who is performing a ISO 485 mail sample sizes. If the total standard deviation, σ_t , is difwork task associated with that machine and site hai/catalog/stand for the standard deviation, σ_M , the risk d33e249eb760pfgrejection9should be estimated on the basis of both stan-

3.19 specified position: A position defined in relation to a machine, including, but not limited to, an operator's position. The position can be a single, fixed point, or a combination of points along a path or on a surface located at a specified distance from the machine, as described in the relevant noise test code, if any.

In ISO 7779 and ISO 9296, positions on the NOTE 11 path are identified as "bystander positions".

3.20 standard deviation of repeatability, σ_r : Standard deviation of noise emission values obtained under repeatability conditions; that is the repeated application of the same noise emission measurement method on the same noise source within a short interval of time under the same conditions (same laboratory, same operator, same apparatus).

In this International Standard, the symbol σ is NOTE 12 used for a standard deviation of a population and the symbol s for a standard deviation of a sample.

3.21 standard deviation of reproducibility, σ_R : Standard deviation of noise emission values obtained under reproducibility conditions; that is, the repeated dard deviations, σ_{t} and σ_{M} .

Typical values of $\sigma_{\rm M}$ range from 1,5 dB to 3,5 dB if the measurement test code is of grade 1 or grade 2 accuracy (employing precision or engineering methods, respectively); if the test code is of grade 3 accuracy (employing a survey method), then typical values of $\sigma_{\rm M}$ may be much higher. Extensive testing may be required to establish the value of $\sigma_{\rm M}$ for a family of machines.

4 Noise emission declarations

Noise emission declarations shall consist of either declared single-number noise emission values or declared dual-number noise emission values. The selection of the appropriate form of noise declaration is made in the relevant noise test code. The noise emission values to be declared are one or more of the A-weighted sound power level, $L_{\rm WA},$ the A-weighted time-averaged emission sound pressure level, L_{pA} , or the C-weighted peak emission sound pressure level, $L_{p\mathrm{C,peak}}$, from measurements of the highest practicable grade of accuracy.

NOTE 14 It is recommended to use engineering grade accuracy (grade 2) or better.

Noise emission values shall be declared for each operating mode specified in the appropriate noise test code. If no noise test code exists, the guidance given in the relevant basic standards (the ISO 3740 or ISO 9614 series, and the ISO 11200 series) shall be followed.

The noise emission declarations shall be such as to allow the values to be verified according to the procedures of this International Standard. Guidelines for determination of declared noise emission values, consistent with ISO 7574-2 and ISO 7574-4, are given in annex A.

NOTE 15 The specifications of ISO 7574-2 and ISO 7574-4, giving greater detail on noise declaration than annex A of this International Standard, may be followed if required in the case of a particular family of machinery or equipment.

5 Presentation of noise emission declarations

Noise emission declarations shall contain the follow-RD PREVIEW ing:

- a) identification of the machinery and equipment **6 Verification of noise emission** with sufficient detail to determine the applicability of the declared noise emission values; ISO 4871:1996 https://standards.iteh.ai/catalog/standards/sist/586c3805-4815-4b85-9efl-
- b) identification of the respective noise test 200 and 70 / iso-4871-199 any, and the basic standards;
- c) identification of the respective operating modes; and
- d) either
 - 1) the words "DECLARED SINGLE-NUMBER NOISE EMISSION VALUES in accordance with ISO 4871", followed by one or more of the declared single-number noise emission values L_{WAd} , L_{pAd} and $L_{pC,peak,d}$ (see B.1), or
 - 2) the words "DECLARED DUAL-NUMBER NOISE EMISSION VALUES in accordance with ISO 4871", followed by one or more of the declared dual-number noise emission values L_{WA} , L_{pA} and $L_{pC,peak}$ and their respective uncertainties K_{WA} , K_{pA} and $K_{pC,peak}$ (see B.2).

In the event of the use of the dual-number noise emission declaration, the measured noise emission value L, and the associated uncertainty K, shall always be given together. If the single-number noise emission declaration is used, it shall always consist of L_d .

NOTES

16 The manufacturer or supplier may optionally provide frequency band data, in addition to the information which has to be declared.

17 The preferred declared noise emission quantity is the declared A-weighted sound power level, either L_{WAd} or L_{WA} and K_{WA} . The A-weighted sound power level is the basic noise emission quantity adopted in the ISO 7574 series, and the one which most accurately tracks changes in noise emission from one piece of machinery and equipment to another.

18 Noise declaration for computer and business equipment should be in accordance with ISO 9296.

19 The C-weighted peak emission sound pressure levels yielded by the products of many industries are so low as to make declaration of this quantity unnecessary. In such cases, general information on the C-weighted peak emission sound pressure levels should be contained in the noise test codes for the specific families of machinery and equipment produced by these industries.

71-1996 6.1 General

The quantity to be verified is either the declared single-number noise emission value L_d , or the sum of the measured noise emission value L, and the uncertainty K, depending on the form of the noise emission declaration. Verification shall be effected by means of noise measurements made according to the same noise test code, or, if there is no noise test code, according to a basic measurement standard with the same or better grade of accuracy, and under the same machinery or equipment operating conditions as those to which the declared noise equation values refer.

NOTE 20 Verification of the noise emission declaration using a basic test method with a lower grade of accuracy may be effected by agreement between the manufacturer and user, providing allowance is made for the lower accuracy.

The choice of verification on a single machine or a batch of machines is made in the relevant noise test code.

The procedures given in 6.2 and 6.3 are designed for inspection under reproducibility conditions.

The following procedure for verifying L_d or (L + K) for an individual machine is consistent with ISO 7574-2.

The procedures for batches of machines are consistent with ISO 7574-4 using double sampling inspection, the sample size of three machines being equivalent to that of the single sampling inspection procedure. The verification procedures ensure that there is a 95 % probability of acceptance for batches of machines if no more than 6,5 % of the equipment in a batch has measured noise emission values greater than L_d or (L + K), as appropriate. The criteria given in 6.3 for batches of machines are based on the double sampling inspection procedure of ISO 7574-4 and a reference standard deviation (defined in 3.24) of 2,5 dB.

NOTES

21 In the calculations in 6.3, a reference standard deviation, $\sigma_{\rm M}$, of 2,5 dB has been used and the result has been rounded to the nearest 0,5 dB.

22 For a certain family of machines, if a specific value of $\sigma_{\rm M}$ has been determined (e.g. by interlaboratory tests) and

6.2 Verification procedure for a single machine

a measured noise emission value of the verification, L_{1} , the criterion to be satisfied in order that the declaration for the whole batch is verified is either

$$(L_{\rm d}-L_{\rm 1}) \geqslant$$
 3,0 dB

or

$$[(L+K)-L_1] \ge 3,0 \text{ dB}$$

as appropriate.

The batch is rejected if the measured noise emission value of the verification, L_1 , satisfies either the criterion

$$(L_{\rm d} - L_{\rm 1}) < -0.5 \ {\rm dB}$$

or

 $[(L + K) - L_1] < -0.5 \text{ dB}$

as appropriate.

lf is given in a relevant noise test code, it may be more appropriate to use that value for the verification. STANDARD $0.5 \le (E_d - L_1) \le 3.0$ dB (standards.iteh.ai) $-0.5 \le [(L+K) - L_1] < 3.0 \text{ dB}$ <u>ISO 4871:1996</u>

If one machine is evaluated, yielding a measured noise emission value of the verification, L_1 , the criterion to be satisfied in order for the noise emission declaration of this single machine to be verified is either

$$L_1 \leqslant L_d$$

or

$$L_1 \leqslant (L+K)$$

as appropriate.

This procedure is consistent with the procedure for verifying L_c for an individual machine given in ISO 7574-2.

6.3 Verification procedure for a batch of machines

6.3.1 Verification based on measurements on one machine from a batch

If one machine is evaluated in order to verify the noise emission declaration for a batch of machines, yielding

on one machine only. In that case, refer to 6.3.2. The single machine used for the measurements is, however, verified individually if it fulfils the requirement given in 6.2.

NOTE 23 The derivations of the above values 3,0 dB and 0,5 dB are given in C.1.

6.3.2 Verification based on measurements on three machines from a batch

If the decision for the verification of the batch cannot be made based on the measurements on one machine, an additional two machines from the batch shall be evaluated. The noise emission declaration for the whole batch is verified if the average noise emission value \overline{L}_{i} , calculated from the three individual values L_{i} using the equation

$$\overline{L} = \frac{1}{3} \sum_{i=1}^{3} L_i$$

satisfies either the criterion

$$(L_{\rm d}-\overline{L})$$
 \geqslant 1,5 dB

https://standards.iteh.ai/catalog/standards/sigt/5866380574815-498519661tion of the batch of mad33e249eb760/isn-4871-1996 be made based on the measurement or

$$[(L+K)-\overline{L}] \ge 1.5 \text{ dB}$$

as appropriate.

Even if the noise emission declaration of the batch is not verified, those of the individual machines on which measurements have been made are still verified individually if they fulfil the requirement given in 6.2.

NOTE 24 The derivation of the value 1,5 dB above is given in C.2.
