

Designation: E471 – 22

# Standard Test Method for Obtaining Char Density Profile of Ablative Materials by Machining and Weighing<sup>1</sup>

This standard is issued under the fixed designation E471; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon ( $\epsilon$ ) indicates an editorial change since the last revision or reapproval.

## INTRODUCTION

The ablation characteristics of charring materials must be well known in order to design the material for a specific set of environmental conditions. The char density profile and the environmental conditions under which it was formed can provide useful information about the ablation performance.

A method of obtaining the char density profile from a charred sample of material is described in the following sections. Some chars are very friable and are easily broken before they can be measured. Other chars are relatively strong and can be handled with ease. The type of char density profile measurement described in this method is applicable if the char is strong enough to be machined without breaking.

## 1. Scope

1.1 This test method covers the determination of the char density profile of a charred ablator that can be used with the following limitations:

1.1.1 The local surface imperfections must be removed, and the char must be able to be machined off in a plane parallel to the char-virgin material interface before the density profiles can be determined.

1.1.2 The char must be strong enough to withstand the machining and handling techniques employed.

1.1.3 The material should have orderly density variations. The total thickness of the char and degradation zone must be larger than the machining thicknesses required.

1.2 *Units*—The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.2.1 *Exception*—Certain inch-pound equivalent units are included in parentheses for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety, health, and environmental practices and determine the applicability of regulatory limitations prior to use.*

1.4 *This international standard was developed in accordance with internationally recognized principles on standard-*

*ization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.*

## 2. Summary of Test Method

2.1 Density variation throughout a charred ablator material is determined by successively measuring, machining, and weighing a sample of known size to obtain the density of the material removed by machining.

## 3. Apparatus

3.1 The apparatus required for this method includes a laboratory balance capable of measuring to the nearest 0.0001 g, and a machining technique capable of removing material in increments as small as 0.025 mm (0.001 in.). For example, flat specimens can be machined with a surface grinder using a medium fine grit ceramic grinding wheel of a soft grade dressed to the proper contour. Cylindrical specimens can be mounted in a lathe and the char can be removed with a sharp carbide or diamond tip tool.

## 4. Sampling

4.1 The charred sample selected for machining and weighing should be taken from a representative section of the ablated specimen where the environmental conditions are well known, and where the surface is parallel to the char-virgin material interface. Where large sections are available, this condition is usually met. For small samples which have been exposed to varying environmental conditions along the length of the sample, the sample size will be smaller.

<sup>1</sup> This test method is under the jurisdiction of ASTM Committee E21 on Space Simulation and Applications of Space Technology and is the direct responsibility of Subcommittee E21.08 on Thermal Protection.

FIG. 1 Typical Specimen for Measuring Char Density Profile

## 5. Test Specimens

5.1 A typical specimen size obtained from a channel, pipe flow, or rocket motor section may be 12.7 by 12.7 mm (0.5 by 0.5 in.), or 12.7 mm (0.5 in.) in diameter. The sample thickness is determined by the available thickness of material. Smaller or larger samples can be used depending upon the accuracy, weighing apparatus, and specimen size. Larger samples reduce edge effects. Excess virgin material should be eliminated, if possible.

5.2 The specimen is rough-cut out of the ablated section, and then machined so as to make the sides perpendicular and the front surface parallel to the char-virgin interface as shown in Fig. 1.

5.3 For simplicity and ease of handling, the base of the sample (the backface or side opposite the charred surface) may be cemented to a thin piece of steel. This permits the sample to be handled with tweezers and facilitates the mounting of the sample on a magnetic chuck or other mounting jig for machining the surface from a fixed reference plane.

## 6. Procedure

### 6.1 Sample Preparation:

6.1.1 Take the dimensions of the specimen with micrometers or other suitable measuring devices to the nearest 0.025 mm (0.001 in.), and record. Weigh the specimen on a balance to the nearest 0.0001 g and record the weight. If the sample has not been prepared with parallel sides, take additional measurements to determine the surface area being removed. Section 6.4 has additional comments on moisture content and chemical reactions of some chars with atmospheric constituents.

6.1.2 Take care to prevent breaking off any of the char during the measuring or weighing operations.

### 6.2 Machining:

6.2.1 If the char-virgin material interface is not parallel to the front surface, then machine the latter parallel to the interface.

6.2.2 It is preferable to have a grinding machine, or lathe set up specifically for this machining operation so as to leave the settings untouched between weighings. For a surface grinding machine, advance the grinding wheel dressed flat to  $\pm 0.0127$  mm (0.0005 in.) in 0.025 mm (0.001 in.) increments until a suitable amount has been removed. This is usually about 0.254 mm (0.010 in.). After the surface has been cleaned up (when

the machining process has resulted in a continuous surface all over the specimen) allow the specimen to stabilize at the selected relative humidity and temperature conditions before measuring and weighing. For consistency, remove the machining dust after each machining operation with about 34 kPa (5 psi) air through a nozzle held about 25 mm (1 in.) from the machined surface.

### 6.3 Dimensional Measurements:

6.3.1 The increment of material removed between weighings is usually 0.254 mm (0.010 in.) depending upon the total char thickness and the uniformity of the charred specimen. If the char is relatively uniform in density down to the char-virgin material interface, increase the machining increments. If the char-virgin material interface is sharply defined, take smaller machining increments. Exercise extreme care when making the dimensional measurements with a micrometer to avoid crushing the char.

### 6.4 Weight Measurements:

6.4.1 Maintain the specimen at constant humidity conditions (ideally dry) during the machining, measuring, and weighing operation. A freshly charred ablator has a chemically active surface like that of activated charcoal. Previous experience indicates equilibrating the specimen to 50 % relative humidity and 20 °C (70 °F) dry should yield good results.<sup>2</sup> Make a separate measurement on the char to determine how much moisture is contained at this relative humidity.

6.4.2 Some chars have chemically active species which are unstable in atmospheric conditions. Special handling techniques would be required for these chars and this is beyond the scope of this test method.

6.4.3 Repeatedly machine, measure, and weigh the specimen until the char and the char-virgin material interface has been removed, and the density approaches the virgin material density.

## 7. Calculation

7.1 Determine the average density of the material removed using the weight and dimensional changes as follows:

$$\rho = \frac{(W_1 - W_2)}{A(H_1 - H_2)} \quad (1)$$
