Designation: ~~D7757 – 17~~ D7757 – 22

Standard Test Method for
Silicon in Gasoline and Related Products by Monochromatic Wavelength Dispersive X-ray Fluorescence Spectrometry[1]

This standard is issued under the fixed designation D7757; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of total silicon by monochromatic, wavelength-dispersive X-ray fluorescence (MWDXRF) spectrometry in naphthas, gasoline, gasoline-ethanol blends, reformulated gasoline (RFG), ethanol and ethanol-fuel blends, and toluene at concentrations of 3 mg⁄kg to 100 mg⁄kg. The precision of this test method was determined by an interlaboratory study using representative samples of the liquids described in 1.1 and 1.2. The pooled limit of quantitation (PLOQ) was estimated to be 3 mg⁄kg.

NOTE 1—Volatile samples such as high-vapor-pressure gasolines or light hydrocarbons might not meet the stated precision because of the evaporation of light components during the analysis.

NOTE 2—Aromatic compounds such as toluene are under the jurisdiction of Committee D16 on Aromatic Hydrocarbons and Related Chemicals. However, toluene can be a contributor to silicon contamination in gasoline (see ~~4.4~~5.4), thus its inclusion in this test method.

1.2 Gasoline samples containing ethanol and other oxygenates may be analyzed with this test method provided the matrix of the calibration standards is either matched to the sample matrices or the matrix correction described in Annex A1 is applied to the results. The conditions for matrix matching and matrix correction are provided Section ~~5~~6, Interferences.

1.3 Samples with silicon concentrations above 100 mg⁄kg can be analyzed after dilution with appropriate solvent. The precision and bias of silicon determinations on diluted samples have not been determined and may not be the same as shown for neat samples (Section ~~16~~17).

1.4 A fundamental assumption in this test method is that the standard and sample matrices are well matched, or that the matrix differences are accounted for (see ~~13.5~~14.5). Matrix mismatch can be caused by C/H ratio differences between samples and standards or by the presence of other interfering heteroatoms; observe the cautions and recommendations in Section ~~5~~6.

1.5 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate ~~safety~~ safety, health, and ~~health~~environmental practices and determine the applicability of regulatory limitations prior to use.*

1.7 *This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.*

A Summary of Changes section appears at the end of this standard.

3. Terminology

3.1 *Definitions:*

3.1.1 For definitions of terms used in this test method, refer to Terminology D4175.

4. Summary of Test Method

4.1 A monochromatic X-ray beam with a wavelength suitable to excite the K-shell electrons of silicon is focused onto a test specimen contained in a sample cell (see Fig. 1). The fluorescent Kα radiation at 0.713 nm (7.13 Å) emitted by silicon is collected by a fixed monochromator (analyzer). The intensity (counts per second) of the silicon X-rays is measured using a suitable detector and converted to the concentration of silicon (mg/kg) in a test specimen using a calibration equation.

5. Significance and Use

5.1 This test method provides rapid and precise measurement of total silicon in naphthas, gasoline, gasoline-ethanol blends, RFG, ethanol and ethanol-fuel blends, and toluene with minimum sample preparation. Typical analysis time is 5 min to 10 min per sample.

FIG. 1 Schematic of the MWDXRF Analyzer

---

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

5.2 Excitation by monochromatic X-rays reduces background, simplifies matrix correction, and increases the signal/background ratio compared to polychromatic excitation used in conventional WDXRF techniques.[3]

5.3 Silicone oil defoamer can be added to coker feedstocks to minimize foaming in the coker. Residual silicon in the coker naphtha can adversely affect downstream catalytic processing of the naphtha. This test method provides a means to determine the silicon content of the naphtha.

5.4 Silicon contamination of gasoline, gasoline-ethanol blends, denatured ethanol, and their blends has led to fouled vehicle components (for example, spark plugs, exhaust oxygen sensors, catalytic converters) requiring parts replacement and repairs. Finished gasoline, gasoline-ethanol blends, and ethanol-fuel blends can come into contact with silicon a number of ways. Waste hydrocarbon solvents such as toluene can be added to gasoline. Such solvents can contain soluble silicon compounds. Silicon-based antifoam agents can be used in ethanol plants, which then pass silicon on to the finished ethanol-fuel blend. This test method can be used to determine if gasoline, gasoline-ethanol blends, and ethanol-fuel blends meet specifications with respect to silicon content of the fuel, and for resolution of customer problems.

5.5 Some silicon compounds covered by this test method are significantly more volatile than the silicon compounds typically used for the preparation of the calibration standards. Volatile compounds may not meet the stated precision from this test method because of selective loss of light materials during the analysis.

6. Interferences

6.1 Differences between the elemental composition of test samples and the calibration standards can result in biased silicon determinations. For fuels within the scope of this test method, the only important elements contributing to bias resulting from differences in the matrices of calibrants and test samples are hydrogen, carbon, and oxygen. A matrix-correction factor (C) may be used to correct this bias; the calculation is described in Annex A1. For general analytical purposes, the matrices of test samples and the calibrants are considered to be matched when the calculated correction factor C is within 0.95 to 1.05. No matrix correction is required within this range. A matrix correction is required when the value of C is outside the range of 0.95 to 1.05. For most testing, matrix correction can be avoided with a proper choice of calibrants. For example, Fig. 2 and the calculation in Annex A1 show that a calibrant with 87.5 % by mass carbon and 12.5 % by mass hydrogen can cover non-oxygen containing samples with C/H ratios from 5.0 to 11.0, which corresponds to a correction factor range of 0.95 to 1.05.

**FIG. 2 Matrix Correction for a Test Sample versus C/H and Total Oxygen Content Using Chromium Kα for the Excitation Beam**

[3] Bertin, E. P., *Principles and Practices of X-ray Spectrometric Analysis*, Plenum Press, New York, 1975, pp. 115–118.

6.2 Fuels containing large quantities of ethanol, such as ethanol fuel blends, denatured fuel ethanol, and gasoline-ethanol blends (see Specifications D4806 and D5798), can have a high oxygen content leading to significant absorption of silicon Kα radiation and low silicon results. Such fuels may be analyzed using this test method provided either that correction factors (see Table 1 and Table 2) are applied to the results or by using calibration standards that are matrix matched to the test sample. For gasoline samples with oxygenates, up to 3.1 % by mass oxygen can be tolerated for test samples with the same C/H ratio as the calibrants.

6.2.1 For test samples with high oxygenate content, such as denatured fuel ethanol and ethanol fuel blends (see Specifications D4806 and D5798), ethanol-based calibrants may be used provided the correction factors as described in 5.16.1 are applied to the results. Table 1 and Table 2 show the correction factor that should be applied to the measurement results of the gasoline-ethanol and ethanol fuel blends if they are measured using either an *iso*octane or ethanol calibration curve.

NOTE 3—Alcohol based calibration standards may be preferred for test samples containing a high oxygenate content.

6.3 To minimize any bias in the results, use calibration standards prepared from silicon-free base materials of the same or similar elemental composition as the test samples.

6.3.1 When diluting samples, use a diluent with an elemental composition the same or similar to the base material used for preparing the calibration standards.

6.3.2 A base material for gasoline may be simulated by mixing 2,2,4-trimethylpentane (*iso*octane) and toluene in a ratio that approximates the expected aromatic content of the samples to be analyzed.

7. Apparatus

7.1 *Monochromatic Wavelength Dispersive X-ray Fluorescence (MWDXRF) Spectrometer*[4], equipped for X-ray detection at 0.713 nm (7.13 Å). Any spectrometer of this type may be used if it includes the following features, and the precision and bias of test results are in accordance with the values described in Section 1617.

7.1.1 *X-ray Source,* capable of producing X-rays to excite silicon. X-ray tubes with a power >20 W capable of producing Rh Lα, Pd Lα, Ag Lα, Ti Kα, Sc Kα, or Cr Kα radiation are recommended for this purpose.

7.1.2 *Incident-beam Monochromator,* capable of focusing with an effective collection solid angle greater than 0.05 sr and selecting a single wavelength of characteristic X-rays from the source onto the specimen. A monochromatic beam is considered to be monochromatic when it has an energy bandwidth (Full Width Half Maximum) less than ±1.5 % relative to the selected energy and containing more than 98 % flux of the spectrum of the excitation beam which is incident on the sample.

TABLE 1 Correction Factors for Gasoline-Ethanol and Ethanol Fuel Blends Measured on an *Iso*octane Calibration Curve

NOTE 1—Determine the correction factor in the table below by finding the known ethanol content of the test specimen (for example, 15 % by mass) as the sum of the value in the first column and the value in the first row (for example, 15 = 10+5). The intersection of these two values is the correction factor (for example, 1.0844). Apply the correction according to 13.514.5. Refer to 7.78.7 and 11.112.1 for *iso*octane calibration.

Ethanol, % by mass	0 %	1 %	2 %	3 %	4 %	5 %	6 %	7 %	8 %	9 %
0 %	1.0000	1.0056	1.0112	1.0169	1.0225	1.0281	1.0337	1.0394	1.0450	1.0506

70 %	0.8920	0.8956	0.8992	0.9028	0.9064	0.9100	0.9136	0.9172	0.9208	0.9244
80 %	0.9280	0.9316	0.9352	0.9388	0.9424	0.9460	0.9496	0.9532	0.9568	0.9604
90 %	0.9640	0.9676	0.9712	0.9748	0.9784	0.9820	0.9856	0.9892	0.9928	0.9964

7.1.3 *Optical Path,* designed to minimize the absorption along the path of the excitation and fluorescent beams using a helium or vacuum atmosphere.

7.1.4 *Fixed-Channel Monochromator,* suitable for dispersing silicon Kα X-ray photons with an effective collection solid angle greater than 0.3 sr.

7.1.5 *Detector,* designed for efficient detection of silicon Kα X-ray photons.

7.1.6 *Single-Channel Analyzer,* an energy discriminator to monitor only silicon radiation.

7.1.7 *Removable Sample Cell,* compatible with the sample and the geometry of the MWDXRF spectrometer. A disposable cell is recommended.

7.1.8 *X-Ray Transparent Film,* for containing and supporting the test specimen in the sample cell (see ~~6.1.7~~7.1.7) while providing a low-absorption window for X-rays to pass to and from the sample. Use an X-ray transparent film resistant to chemical attack that does not contain a listed silicon impurity. Follow manufacturer's recommendations for appropriate film types.

8. Reagents and Materials

8.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society where such specifications are available.[5] Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

8.2 *Calibration-Check Samples,* for verifying the accuracy of a calibration. The check samples shall have known silicon content and not be used in determining the calibration curve. A standard from the same reliable and consistent source of calibration standards used to determine the calibration curve is convenient to validate the calibration.

8.3 *Octamethylcyclotetrasiloxane (D4),* a high-purity material (typical purity 98 %), is known to be suitable for making silicon calibration standards. Use the known silicon concentration and the material purity when calculating the exact concentrations of silicon in calibration standards. (**Warning—** Octamethylcyclotetrasiloxane is harmful if swallowed or absorbed through skin. It is an eye irritant and may cause skin irritation.)

8.4 *Drift Correction Monitor(s) (Optional)*—, to determine and correct instrument drift over time (see ~~11.4~~12.4, ~~12.1~~13.1, and ~~13.1~~14.1). Various forms of stable (with respect to repeated exposure to X-rays) silicon-containing materials are suitable drift

---

[5] *Reagent Chemicals, American Chemical Society Specifications,* *ACS Reagent Chemicals, Specifications and Procedures for Reagents and Standard-Grade Reference Materials,* American Chemical Society, Washington, DC. For ~~Suggestions~~ suggestions on the testing of reagents not listed by the American Chemical Society, see ~~Annual~~ *Analar Standards for Laboratory Chemicals*, BDH Ltd., Poole, Dorset, U.K., and the *United States Pharmacopeia and National Formulary*, U.S. Pharmacopeial Convention, Inc. (USPC), Rockville, MD.

correction monitors; for example, liquid petroleum, solid, pressed powder, metal alloy, and fused glass. The count rate displayed by the monitor sample, in combination with a convenient count time (T), shall be sufficient to give a relative standard deviation (RSD) of less than 1 % (see Appendix X1).

8.4.1 Calibration standards may be used as drift correction monitors. Because it is desirable to discard test specimens after each determination, a lower cost material is suggested for use over time. Any stable material meeting the recommendations of 7.48.4 or 7.4.18.4.1 may be used for monitoring of drift on a given day when samples are being analyzed.

NOTE 4—The effect of drift correction on the precision and bias of this test method has not been studied.

8.4.2 Drift correction may be done automatically if the instrument embodies this option, although the calculation may be readily done by conventional methods of data reduction and processing.

8.5 *Quality-Control (QC) Samples,* for use in establishing and monitoring the stability and precision of an analytical measurement system (see Section 1516). Use homogeneous materials, similar to samples of interest and available in sufficient quantity to be analyzed regularly for a long period of time.

8.5.1 Verification of system control through the use of QC samples and control charting is highly recommended.

NOTE 5—Suitable QC samples can be prepared by combining retains of typical samples.

8.6 *Ethanol,* use a high purity grade and account for its silicon content when calculating the silicon concentrations of the calibration standards. (**Warning—**Ethanol is flammable and harmful if swallowed or inhaled. It is an eye irritant and may cause skin irritation.)

8.7 *2,2,4-Trimethylpentane (Isooctane),* use a high purity grade and account for its silicon content when calculating the silicon concentration of the calibration standards. (**Warning—***Iso*octane is flammable and harmful if swallowed or inhaled. It is an eye irritant and may cause skin irritation.)

8.8 *Toluene,* use a high purity grade and account for its silicon content when calculating the silicon concentration of the calibration standards. (**Warning—**Toluene is flammable and harmful if swallowed or inhaled. It is an eye irritant and may cause skin irritation.)

8.9 *Helium,* (for units that require helium per manufacturer), minimum purity 99.9 %, for use as an optical path.

9. Hazards

9.1 (**Warning—**Exposure to excessive quantities of X-ray radiation is injurious to health. The operator needs to take appropriate actions to avoid exposing any part of his/her body, not only to primary X-rays, but also to secondary or scattered radiation that might be present. The X-ray spectrometer should be operated in accordance with local and national regulations governing the use of ionizing radiation.)

9.2 Consult current health and safety regulations such as OSHA, suppliers' Material Safety Data Sheets and local regulations for all materials used in this test method.

10. Sampling and Sample Handling

10.1 Sample fuel according to the procedures in Practices D4057 or D4177.

10.2 Use the utmost care in sampling and handling gasoline to prevent evaporation of light ends which could change the concentration of silicon in the sample. Store gasoline in a leak tight container at 0 °C to 4 °C until ready for analysis. If possible, maintain at this temperature throughout any transfer and handling processes. Allow samples maintained at 0 °C to 4 °C to come to room temperature before testing, and expose these materials to ambient conditions only as long as necessary to obtain a sample for analysis. Analyze test specimens as soon as possible after sub-sampling from bulk container. Do not allow bulk container to remain uncovered any longer than is needed to obtain desired sub-samples.

10.3 For specimen preparation, see 10.211.2.

10.3.1 Because impurities and thickness variations can occur in commercially available transparent films and vary from lot to lot, use calibration-check samples (see 7.28.2) to verify calibration integrity after starting each new batch of film or if the type and thickness of the window film is changed.
