

Designation: ~~D2454 – 18~~ D2454 – 23

## Standard Practice for Determining the Effect of Overbaking on Organic Coatings<sup>1</sup>

This standard is issued under the fixed designation D2454; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

### 1. Scope\*

1.1 This practice covers the determination of the time-temperature effect of overbaking on the physical and chemical properties of organic coatings.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety, health, and environmental practices and determine the applicability of regulatory limitations prior to use.* Specific hazard statements are given in Section 7.

1.4 *This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.*

### 3. Terminology

#### 3.1 Definitions:

3.1.1 *overbaking, n*—an exposure of the coating to a moderately higher temperature or to a longer period of baking, or both, than recommended by the manufacturer of the coating for normal curing.

##### 3.1.1.1 Discussion—

This condition is in contrast to “heat resistance” which is a parameter relating to the service life of a coating.

### 4. Summary of Practice

4.1 Four panels are prepared and baked at the schedule normally recommended for the coating. Two of the panels are then removed and the remaining two are subjected to an additional overbake in which the time and temperature are mutually agreed upon between the purchaser and the seller. The sets of panels, after a suitable conditioning interval, are then evaluated for the properties that are compatible with the substrate. Among these are gloss, color, flexibility, adhesion, impact resistance, and resistance to reagents.

NOTE 1—Glass substrates should not be tested for impact, and zinc-coated substrates can influence both flexibility and impact.

### 5. Significance and Use

5.1 Most coatings are designed for a specific baking time and temperature. For a variety of reasons (line stoppages, rerouting back through ovens, oven overheating, etc.) the prescribed time or temperature, or both, of the bake is often exceeded. This practice has been found to be useful in evaluating the effects of overbakes on coatings.

### 6. Materials

6.1 *Standard Baking-Type Coating* mutually agreed upon between the purchaser and the seller.

### 7. Hazards

7.1 The flash points of most solvents used in many organic coatings and related products are low enough that adequate ventilation is needed to avoid exceeding 25 % of the lower explosive limits of the solvents when test panels are being prepared and baked. As these materials are considered toxic, take care to avoid inhalation of solvent vapor and unnecessary contact of solvent with the skin.

### 8. Procedure

#### 8.1 Application of Organic Coating:

8.1.1 Apply coatings to steel panels prepared in accordance with Practice [D609](#).

8.1.2 Apply coatings to zinc-coated surfaces prepared in accordance with Guide [D7396](#) or Practice [D6386](#), when zinc has been applied by the hot-dip method or by electroplating.

8.1.3 Apply coatings to nonpassivated galvanized steel prepared in accordance with Guide [D7396](#) or Practice [D2201](#), when the zinc is applied by a continuous galvanizing method using an aluminum-bearing zinc.

8.1.4 Apply coatings to aluminum surfaces on all-aluminum materials prepared in accordance with Practices [D1730](#).

8.1.5 Apply coatings to hot-dip aluminum coated surfaces prepared in accordance with Practices [D1731](#).

8.1.6 In cases where a primer is used in practice under the topcoat, apply the entire system to the panels. The film thickness of each coat shall be mutually agreed upon between the purchaser and seller, but, in the absence of such agreement, the total thickness shall be 22 mils  $\pm$  0.2 mils (50(50  $\mu$ m  $\pm$  5  $\mu$ m).

8.1.7 In instances where clear coatings are to be tested, they may be applied to aluminum or white carrara glass, one side of which has been polished to a smooth, high-gloss finish. Other selected ~~substrate~~ substrate previously agreed upon between the purchaser and the seller may also be used. In the absence of a specific agreement between the purchaser and the seller in regard to film thickness, apply the coatings by automatic spray. (Refer to Practices **D823**, Method A) at a dry film thickness of 22 mils  $\pm$  0.2 mils (50(50  $\mu$ m  $\pm$  5  $\mu$ m). Multiple coats may be used to obtain this film thickness where necessary due to the nature of the coating material (**Note 2**). Manual spray application or the drawdown method with wire-wound draw bars may be used when automatic equipment is not available.

**NOTE 2**—Dry film thickness should be measured in accordance with Test Method **D1005** or Practice **D7091**, whichever is applicable. The adhesion, flexibility, and color can vary considerably with thickness.

## 8.2 Baking:

8.2.1 The baking schedule for each coating including primer, topcoat, and primer/topcoat systems shall be mutually agreed upon between the purchaser and the seller and shall include the following:

8.2.1.1 *Normal Baking Schedule (Time and Temperature)* recommended for the development of optimum film properties, and

8.2.1.2 *Overbaking Cycle*—This cycle shall be within practical limits in order to simulate conditions that might be encountered in actual production where baking oven or conveyor lines, or both might malfunction temporarily due to mechanical or electrical failure.

8.3 Prepare four panels of each coating or coating system and bake them at the schedule normally recommended to obtain optimum properties. Conduct the baking of these panels in a mechanical recirculating air oven set to  $\pm 2^\circ\text{C} \pm 2^\circ\text{C}$  of the specified baking temperature. At the end of the specified time remove two panels from the oven and subject the remaining two to the overbake cycle by:

8.3.1 A continuation of the normal bake but for a previously agreed upon time, for example, 5050 % or 100 % increase in time, or

8.3.2 Resetting the oven temperature to the agreed overbake temperature and then continuing the bake for a specified period of time after the overbake temperature has been reached, or removing the panels until the overbake temperature is reached and then baking them for the agreed upon time.

**NOTE 3**—The conditions described in **8.3.2** are not usually reproducible between laboratories or different ovens because of variations in the heating characteristics of ovens.

8.3.3 After the sets of panels have been baked according to the mutually agreed upon baking cycles, place them in a suitable rack and condition for 24 h at ~~23  $\pm$  2°C and 50~~ 23  $\pm$  2°C and 50  $\pm$  2 °C and 50 %  $\pm$  5 % relative humidity (see Test Methods **D1640**) prior to testing. Other conditioning terms may be agreed upon between the purchaser and the seller.

## 9. Test Methods

9.1 Determine the properties of both sets of panels in accordance with any or all of the following ASTM methods:

9.1.1 *Gloss*—Test Method **D523**.

9.1.2 *Color*—Practice **D1729** (Visual), Practice **E805** (instrumental), or Practice **D2244**.

9.1.3 *Flexibility*—Test Methods **D522** (conical mandrel and cylindrical ~~mandrel~~-mandrel), or, for the coil coating industry, Test Method **D4145** (T-bend testing).
