Designation: F1734 – 24

An American National Standard

Standard Practice for Qualification of a Combination of Squeeze Tool, Pipe, and Squeeze-Off Procedures to Avoid Long-Term Damage in Polyethylene (PE) Gas Pipe[1]

This standard is issued under the fixed designation F1734; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers qualifying a combination of a squeeze tool, a polyethylene gas pipe, and a squeeze-off procedure to avoid long-term damage in polyethylene gas pipe. Qualifying is conducted by examining the inside and outside surfaces of pipe specimens at and near the squeeze to determine the existence of features indicative of long-term damage. If indicative features are absent, sustained pressure testing in accordance with Test Method D1598 is conducted to confirm the viability of the squeeze-off process.

NOTE 1—This practice may be useful for evaluating the effects of squeeze-off of other piping materials. If applied to other piping materials, research testing to confirm the applicability of this practice to other materials should be conducted.

NOTE 2—Qualification of historic pipe should follow the historic version of F1734 closest to the pipe manufactured data.

1.2 This practice is appropriate for any combination of squeeze tool, PE gas pipe, and squeeze-off procedure.

1.3 This practice is for use by squeeze-tool manufacturers and gas utilities to qualify squeeze tools made in accordance with Test Method F1563; and squeeze-off procedures based on with Guide F1041 with pipe manufactured in accordance with Specification D2513.

1.4 Governing codes and project specifications should be consulted. Nothing in this practice should be construed as recommending practices or systems at variance with governing codes and project specifications.

1.5 Where applicable in this practice, "pipe" shall mean "pipe and tubing."

1.6 *Units*—The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.7 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety, health, and environmental practices and determine the applicability of regulatory limitations prior to use.*

1.8 *This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.*

3. Terminology

3.1 *Definitions:*

3.1.1 *squeeze-off, n*—a technique used to temporarily control the flow in a polyethylene pipe by flattening the pipe with a mechanical or hydraulic device.

[1] This practice is under the jurisdiction of ASTM Committee F17 on Plastic Piping Systems and is the direct responsibility of Subcommittee F17.60 on Gas.

Current edition approved April 1, 2024. Published May 2024. Originally approved in 1996. Last previous edition approved in 2019 as F1734 – 19. DOI: 10.1520/F1734-24.

3.1.1.1 *Discussion*—Depending on pipe size and wall thickness, stopping flow completely may not be possible. In some cases, attempting to stop flow may over-compress the pipe walls, permanently damage the pipe and lead to premature failure at the squeeze. Some seepage through the squeeze should be expected especially with larger sizes.

3.1.2 *squeeze process, n*—the combination of the squeeze tool, the pipe being squeezed, and the squeeze-off procedure being used.

3.1.3 *wall compression (WC), n*—the percentage extent to which the pipe walls are compressed when the pipe is squeezed. (See Fig. 1.) It is defined as:

$$WC, \% = \left(1 - \frac{L}{2t}\right) \times 100 \quad (1)$$

where:

L = distance between the squeeze tool bars as shown in Fig. 1, and

t = uncompressed pipe wall thickness, expressed in the same units as L.

3.1.3.1 *Discussion*—When the distance between the squeeze tool bars is greater than twice the wall thickness, the pipe walls are not compressed, which yields a negative value for the wall compression percentage. The value becomes positive when the L value is less than the $2t$ value. Typical squeeze tool stops are set for 30 % or less wall compression based on Specification D2513 maximum wall thickness for pipe size and DR combination. This is a distance between the squeeze bars equal to 70 % of twice the maximum wall thickness for pipe size and DR combination when the squeeze tool is closed to the stops. Maximum wall thickness is the minimum wall thickness plus the wall thickness tolerance of 12 %.

4. Significance and Use

4.1 This practice relies on a screening process using visual inspection followed by 80 °C sustained pressure testing to qualify a squeeze-off process.

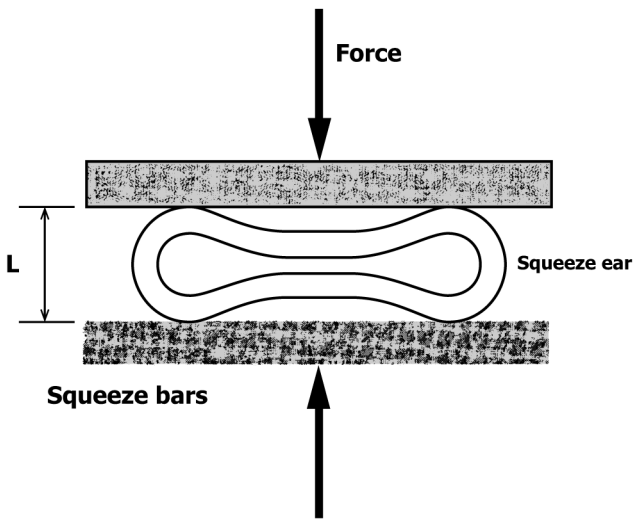

FIG. 1 Definition of Wall Compression

4.2 Squeeze-off is widely used to temporarily control the flow of gas in PE pipe. Squeeze tools vary in squeeze bar shape and size, operating method, and available stop gaps depending on the tool manufacturer and the size of the pipe the tool will be used on. Multiple squeeze tools are required for a range of pipe size and DR combinations. Squeeze-off procedures can vary depending on the tool design, pipe material, pipe size and DR, pipe operating conditions, and pipe environmental conditions.

4.3 Experience indicates that damage leading to gas pipe failure is possible with some combinations of polyethylene material, pipe temperature, tool design, wall compression percentage, and procedure. This practice is useful for determining the suitability of a tool for squeeze-off and for determining acceptable limits for squeeze-off such as acceptable minimum and maximum pipe temperature for squeeze and acceptable line pressure for squeeze. Tests conducted at different pipe temperatures with various sizes of tools and pipes can be used to verify a range of temperatures, tool sizes, and pipe sizes for which the squeeze-off procedure is applicable.

4.4 The area of wrinkling at the ears on the inside diameter (ID) of the pipe and the area on the outside of the pipe opposite the ears are examined. Evidence of any one or a combination of void formation, cracks or extensive localized stress whitening, or failure during sustained pressure testing disqualifies the squeeze-off process.

4.5 Typical unacceptable features implying long-term damage are shown in Appendix X1 photographs.

4.6 Studies of polyethylene pipe extruded in the late 1980s (PE2306 and PE3408) show that damage typically does not develop when the wall compression percentage is 30 % or less, when closure rates are 2 in./minute or less and release rates are 0.5 in./minute or less, and when squeeze bars have radii 4 times or greater than the pipe maximum wall thickness.

4.7 This practice provides a method to qualify a combination of squeeze tool, pipe size and material, and squeeze-off procedure to ensure that long-term damage does not occur. This practice is useful for all polyethylene gas pipe, for all pipe diameters, for new or revised squeeze tool designs, and for new or revised squeeze-off procedures.

5. Apparatus and Materials

5.1 *Squeeze-off Tools,* meeting Specification F1563 that are to be covered by the squeeze-off process.

5.2 *Pipe Cutters and Saws,* capable of cutting the PE pipe.

5.3 *Jeweler's Loupe or (Stereo) Optical Microscope,* providing 10× or higher magnification.

5.4 *Vernier Caliper or Ball-End Micrometer,* with an accuracy of at least 0.001 in.

5.5 *Stopwatch,* that can indicate time to at least the nearest second.

5.6 Sustained pressure testing apparatus in accordance with Test Method D1598.

5.7 Flow testing apparatus similar to that shown in Fig. 2 or Fig. 3.

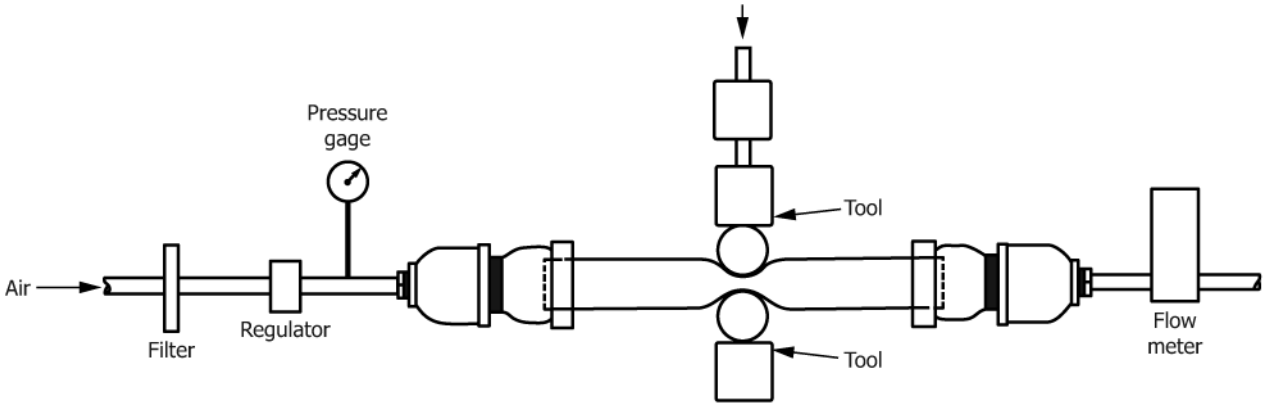

FIG. 2 Typical Flow Testing Apparatus using Flow Meter for Measurement

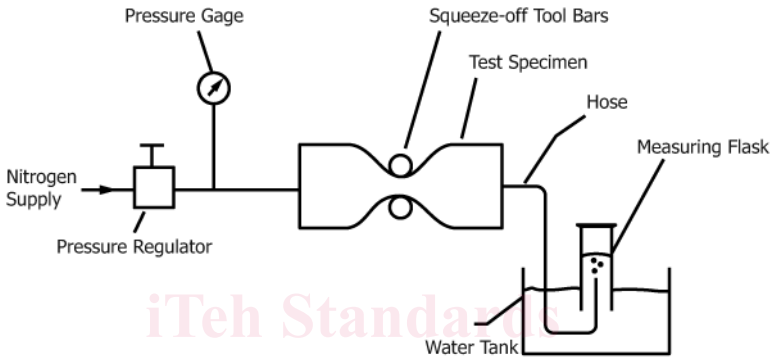

FIG. 3 Typical Flow Testing Apparatus using Water Tank and Flask for Measurement

5.8 Polyethylene pipe meeting Specification D2513.

6. Safety Precautions

6.1 Care should be taken and appropriate personal protective equipment used when working with hydraulic and power tools that may be used in the squeeze-off process. Hearing protection is recommended when compressed gas is discharged from open-ended specimens.

7. Preparation of the Sample and Equipment

7.1 Select nine pipe samples at least 6 pipe diameters long but not less than 1 ft long.

NOTE 3—It is recommended that the thickest wall PE pipe in the operator's system that is acceptable for use with the tool of interest be used for squeeze testing.

7.2 Label the samples then measure outside diameter and wall thickness of samples in accordance with Test Method D2122. Record wall thickness measurements at 15° increments around each sample. Identify the location of maximum wall thickness on each sample.

7.3 Condition samples to the temperature of interest. Experience with smaller-diameter, lower SDR pipe (for example, 2 to 6-in. SDR 11 pipe) indicates that a minimum of 24 h is required for the sample to reach equilibrium. Thicker wall pipe may take longer time to reach thermal equilibrium at the temperature of interest.

NOTE 4—Several pipe temperatures may need to be investigated to determine the limits for which the squeeze-off procedure is applicable.

8. Procedure

8.1 *Gas Flow Control*—Perform an experiment to determine the wall compression required to achieve a desired level of flow control on pipe using the desired tool.

NOTE 5—Historic research has shown that the shape and size of the squeeze bar relative to the pipe wall thickness (D/t) influences the amount of flow controlled and the force needed to shut off the flow. For a given wall compression level, the equivalent width of the squeeze tool bar must increase as internal pressure increases and as wall thickness increases to control flow through a squeezed pipe to a given level.

NOTE 6—In research tests on PE2306 and PE3408 material, a flow of 0.1 ft /h was considered equivalent to stopping flow and wall compression over 30% damaged PE3408 material when pipe temperature was -20 °F.[4,5]

8.1.1 Orient a pipe sample in the flow test apparatus so the thickest portion of the pipe wall forms one of the squeeze-off ears. Locate the squeeze tool at the midpoint of the sample length so that the tool is centered on the sample and square to the centerline of the pipe sample. Closure stops may need to be removed or smaller stops or shims may be needed to obtain the closure distance required for the desired flow control level.

[5] Stephens, D. R., Leis, B. N., Francini, R. B., and Cassady, M. J., Volume 2: Technical Reference on Squeeze-Off of Polyethylene Gas Pipes, Topical Report GRI-92/0147.2, NTIS PB93-161040, Battelle Columbus for Gas Research Institute, October 1992.

8.1.2 Squeeze the pipe at a rate of 2 inches per minute or less as dictated by the procedure of interest, until the pipe walls touch (0% wall compression). Slowly adjust the pressure regulator to increase upstream pressure to the desired line pressure not to exceed the pipes rated pressure. Continue to squeeze pipe until desired flow control is achieved. Record flow rates, distance between squeeze bars, and line pressures in increments up to the desired flow control level for later incorporation into the procedure of interest.

8.1.3 When flow control level is achieved, turn off the supplied gas (air or nitrogen) and allow a minimum squeeze hold time of 30 minutes.

8.1.4 Release the squeeze tool at a rate of 0.5 in. per minute or less as dictated by the procedure of interest.

8.1.5 If re-rounding is included in the procedure of interest, re-round the sample accordingly.

8.1.6 Using Eq 1 and the measured distances between squeeze bars, determine wall compression (*WC*) percentages.

8.1.7 Repeat steps 8.1.1 through 8.1.6 for two additional pipe samples. Determine the average *WC* of all three samples to achieve desired flow control level and call this the nominal level of wall compression, WC_{nom}.

8.2 *Visual Examination*—With the unaided eye, and then with magnification, examine the interior of the sample at each squeeze ear for stress whitening, crazing, or cracking. Examine the exterior of the sample at the squeeze ears for evidence of a dimple centered at the ear. Examine first with the unaided eye. Samples that pass unaided eye visual examination are then visually examined under 10× magnification.

8.2.1 After allowing the three samples to sit undisturbed for 30 minutes, split the samples along their length at 90 degrees to the squeeze "ears" (See Fig. 1) in preparation for visual examination

8.2.2 With the unaided eye, visually examine the samples. Wrinkling of the interior of the squeeze-off ear is expected to occur. Some stress whitening along the ridges and in the valleys of wrinkles is also expected to occur. Stress whitening should be limited to these ridges and valleys in the region where wall thinning occurs in response to the squeeze process. Stress whitening should be diffuse in appearance rather than an intense white band.

8.2.3 Cracking or voids on the inside or a dimple on the outside disqualify the squeeze-off process.

8.2.4 At 10× magnification, examine the interior of the squeeze ear of samples that pass the unaided-eye examination, Cracking or voids disqualify the squeeze-off process.

8.2.5 At 10× magnification, stress whitening strung out along a wrinkle is evidence of damage that can grow with time. Judgment, depending on the severity of the features, the service conditions, and the utility's service record for that pipe, can disqualify the squeeze procedure if such features are found.

8.2.6 General widespread evidence of changes in color, such as intense stress whitening or crazing, is evidence of damage and indicative of possible subsurface damage. Judgment based on experience related to the service record of the pipe involved should be considered in qualifying procedures that produce such features. Examination of cross sections prepared on a cut through the ear can be used to determine if subsurface damage has occurred in such cases. Indications of small voids in cross sections disqualifies the squeeze-off process.

8.2.7 If samples due not pass visual inspection at 10× magnification, repeat steps 8.1.1 through 8.2.6 after changing one or more test parameters such as but not limited to reducing wall compression 3 % to 5 % and flow test pressure, changing tool, or increasing squeeze bar diameter.

8.3 *Sustained Pressure Tests:* If the squeeze-off process is not disqualified by magnified visual examination, squeeze six additional samples in accordance with 8.1.1 through 8.1.5 to WC_{nom}, and then subject them to sustained pressure testing 30 minutes or more after release.

8.3.1 Perform sustained pressure testing on post-squeezed pipe samples in accordance with Test Method D1598 using water as the internal test medium and any of the test conditions in Table 1. Test pressures used shall be calculated using the pipe's actual measured minimum wall thickness and outside diameter measured before the squeeze and applicable test stress.

TABLE 1 Elevated Temperature Sustained Pressure Test Requirements[A]

Condition	Test Temperature °F (°C)	Pipe Material Designation Code PE2708		Pipe Material Designation Code PE4710	
		Hoop Stress,[A] psi (MPa)[B]	Minimum Average Time Before Failure, Hours	Hoop Stress,[A] psi (MPa)[B]	Minimum Average Time Before Failure, Hours
1[C]	76 (80)	670 (4.620)	170	750 (5.170)	200
2	176 (80)	650 (4.480)	340	730 (5.020)	400
3	176 (80)	630 (4.345)	510	705 (4.870)	600
4	176 (80)	610 (4.210)	680	685 (4.175)	800
5	176 (80)	590 (4.070)	850	660 (4.565)	1000
6	176 (80)	580 (4.000)	1000	640 (4.415)	1200

[A] Calculate internal test pressure in accordance with Eq 2:
[B] Test temperature tolerance ±4 °F (±2 °C). Test pressure tolerance ±5psi (±35 kPa); test pressure hoop stress values are rounded to the nearest 5 psi or 5 kPa.
[C] The Hoop Stress at Condition 1 is equivalent to 90 % of the materials HDB at 23 °C. Condition 6 test hoop stress is 85 % of Condition 1 (see Note 7).
