Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

International Standard ISO 7156 was prepared by Technical Committee ISO/TC 155, *Nickel and nickel alloys*.

Annexes A and B of this International Standard are for information only.

Refined nickel — Sampling

1 Scope

This International Standard specifies sampling procedures for up to 25 tonnes (metric tons) of refined nickel of the same composition, size and shape and manufactured under similar conditions of production.

NOTE 1 These procedures are not primarily intended for routine or production lot sampling. However, they can, in certain cases, be used for lot transactions between purchaser and supplier.

2 Normative references

The following standards contain provisions which, through reference in this text, constitute provisions of this International Standard. At the time of publication, the editions indicated were valid. All standards are subject to revision, and parties to agreements based on this International Standard are encouraged to investigate the possibility of applying the most recent editions of the standards indicated below. Members of IEC and ISO maintain registers of currently valid International Standards.

ISO 6283:1979, *Refined nickel*.

ISO 6372-2:1989, *Nickel and nickel alloys — Terms and definitions — Part 2: Refinery products*.

3 Presentation of the product

Refined nickel is usually delivered in one of the following forms:

- whole-sheet cathodes which weigh about 50 kg for a thickness most often between 6 mm and 12 mm;
- drums containing metal pieces. The pieces may be cut cathodes (generally squares with 25 mm, 50 mm or 100 mm edges), briquettes, pellets, shot, granules or powder. The capacity of the drums is most often 50 kg, 250 kg or 1 000 kg.

4 Principle of sampling procedure

4.1 Symbols

For the purposes of this International Standard, the following symbols are used.

U The total number of units of packaging in a lot of 25 tonnes or less. These units may be whole-sheet cathodes or drums.

N The number of units which constitute the primary sample. These N units are the primary increments.

n The number of increments taken from each of the primary increments.

$N \times n$ The number of secondary increments which constitute the secondary sample.

NOTE 2 The justification of the number of primary and secondary increments is given in annex A.

4.2 Sample selection

4.2.1 From the U units contained in the lot, N units are selected to constitute the primary sample. The selection of these units shall respect the rules of random sampling.

4.2.2 From each of the N primary increments, n secondary increments are taken. The $(N \times n)$ secondary increments are combined and constitute the secondary sample.

4.2.3 An adequate complementary treatment to reduce the mass of the secondary sample results in the final laboratory sample for chemical analysis. Cathodes or briquettes are machined to obtain a final sample in the form of fine chips. Pellets, shot or granules are either taken as they are or, when their particle size analysis allows, machined to obtain chips. Powders are homogenized and reduced by riffing until the final sample is obtained.

5 Sample preparation

5.1 The laboratory sample shall be prepared as directed in the clauses dealing with various product forms.

5.2 The laboratory sample shall be of sufficient mass for the chemical analysis planned. For fine chips or powder, it is recommended to divide a sample of at least 200 g between two parties and to keep two portions in reserve in case of dispute. For larger pieces, such as pellets, granules or shot, a minimum mass of 500 g is recommended for each party and for reserve.

5.3 Precautions in sample preparation

5.3.1 Given the high purity of certain qualities of nickel, extremely strict precautions shall be taken in order not to contaminate the sample. Contamination of a sample may occur from tools, utensils and containers used in the sampling operation. Care shall therefore be taken in their selection and use to eliminate or minimize such contamination.

5.3.2 Contamination from cutting tools by elements such as cobalt, chromium, molybdenum, vanadium and tungsten shall be avoided. All machining operations shall be carried out without using lubricants. Experience has shown that high-speed steel cutting tools are better for nickel metal than tungsten carbide tools.

5.4 Final preparation of the laboratory sample

5.4.1 Any sample which has been through a mechanical preparation and, in particular, machining into chips, will inevitably be contaminated on the surface of the metal by, at least, the element iron. It is essential, therefore, that the chips or pieces are cleaned by etching with acid before the test sample is taken for analysis. Unless otherwise specified in the International Standard to be used for the analytical method, the laboratory shall be instructed to clean the test sample as directed in 5.4.2.

5.4.2 Place the chips in a beaker and cover with a few millilitres of concentrated hydrochloric acid. Heat at low temperature and, as soon as dissolution starts (evolution of a few bubbles), add a large quantity of distilled or demineralized water to stop this dissolution. Pour off the diluted acid and wash the chips several times with water, by decantation of the water from the beaker, until acid-free. Wash the chips with high-purity acetone and dry them in a low-temperature oven. Take the test sample to be analysed from the clean chips and keep the remainder for future analyses.

6 Sampling of whole-sheet cathodes

6.1 Primary sampling

6.1.1 Determine the number of units U of whole-sheet cathodes in the lot and select, at random, N units (primary increments) using table 1 as a guide. The number of units in a lot of a given mass and the number of units which constitute the primary sample in table 1 are based on a unit mass of 50 kg.

6.1.2 If the mass per cathode is significantly different from 50 kg, the number of primary increments N shall be selected on the basis of the mass of the lot, as given in column 1 of table 1, and the number N of selected units as given in column 3 of table 1.

6.2 Secondary sampling

6.2.1 From each of the primary increments, n secondary increments as given in column 4 of table 1 shall be taken. Where values of n are coupled, e.g. 3 and 2 or 2 and 1, these are to be distributed randomly among the N primary increments to give $(N \times n)$ as given in column 5 of table 1.

6.2.2 The secondary increments may be taken by any one of the three following methods.

- Drilling a hole through the cathode using a drill, preferably with a diameter between 15 mm and 25 mm. It is possible to obtain chips by appropriate shaping of the drill. Strands of metal shall be cut into small pieces.
- Milling a hole using a cylindrical milling cutter with a diameter between 15 mm and 25 mm to produce chips directly. It may be necessary to drill a small pilot hole, e.g. 2 mm to 3 mm, when using certain designs of cutter.
- Punching out a disc of about 15 mm to 25 mm diameter and milling the disc to produce chips.

6.2.3 For the position of the secondary increment, five geometrical positions are defined on a diagonal of a whole-sheet cathode. Position 1 is taken at a distance of 25 mm to 30 mm from one corner. The distance from position 1 to the centre of the cathode is then divided into five equal intervals to define positions 2 to 5. Thus position 5 is a little before the middle of the cathode. A template may be used to define the positions of the holes along the diagonal of the cathode. The starting corner for the template shall be alternated for each cathode to be sampled, to avoid bias due to starting at the top or bottom of the cathode.

6.2.4 For lots of greater than 3,75 tonnes (where $n = 1$) the secondary increment from the first cathode shall be taken at position 1, from the second at position 2, etc., and back to position 1 for the sixth cathode. When n is greater than 1, the $(N \times n)$ increments shall be distributed among the N cathodes so that positions 1 to 5 are used nearly the same number of times.

6.2.5 Combine the chips from the $(N \times n)$ increments constituting the secondary sample and mix thoroughly. The mass of the chips shall be at least 200 g. Divide the sample by riffing or by fractional shovelling to provide the required number of laboratory samples.

7 Sampling of drums containing forms requiring comminution or machining

Nickel forms such as cathode shapes, briquettes, shot or large granules or pellets require comminution or machining to obtain chips or pieces of a suitable size for the laboratory sample.

7.1 Primary sampling

7.1.1 The number of units U in a lot is the number of drums of given mass. Select the number of drums N to constitute the primary sample as given in table 1 for drums of 50 kg, table 2 for drums of 250 kg and table 3 for drums of 1 000 kg.

7.1.2 For drums of intermediate mass, the numbers N and n shall be adjusted such that the total number of secondary increments $(N \times n)$ is the constant number given in table 1 to table 3 for a given tonnage. The number of units N shall be as high as possible as a function of the number of units U in the lot, and n shall be as small as possible for a given value of $(N \times n)$ specified in table 1 to table 3.

The following example illustrates this point:

5 tonne lot, by drums of 400 kg
 $U = 13$ drums
 From table 2, $N \times n = 23$ and $N = 20$
 but N cannot be greater than U
 Therefore n is 2 or 1 and $N = 13$
 i.e. $n = 2$ for 10 of the drums and 1 for 3 of the drums.

7.2 Secondary sampling

7.2.1 From each drum constituting the primary sample, take at random one or more pieces (secondary increments) as given in table 1 to table 3.

7.2.2 Machine the secondary increments by milling or drilling and cutting, as indicated in 6.2.2, to obtain chips. Briquettes shall be machined from the edge to the centre such that one half of each piece is consumed in the milling process. Large pellets or shot may be pressed between platens for further machining or cutting.

7.2.3 Combine the chips from the $(N \times n)$ increments constituting the secondary sample and mix thoroughly. The mass of the chips shall be at least 200 g. Divide the sample by riffing or by fractional shovelling to provide the required number of laboratory samples.

NOTE 3 For pellet or shot, it may be necessary to increase the value of n to obtain sufficient material for the laboratory samples.

8 Sampling of drums containing forms not requiring comminution or machining

Nickel forms such as powder, fine shot and granules and small pellets can be sampled directly and do not need further preparation such as comminution.

8.1 Primary sampling

8.1.1 Select the number of units (primary increments) to constitute the primary sample as directed in 7.1.1.

8.2 Secondary sampling

8.2.1 One secondary increment of at least 500 g shall be taken from each drum constituting the primary sample. The masses of each of these secondary increments shall be approximately equal. For products which are known to be homogeneous, material may be scooped from the top of the drum. Otherwise, secondary increments shall be obtained by fractional shovelling or by riffing the whole drum.

8.2.2 Secondary increments of nickel powder produced by chemical methods shall be obtained by successive riffing of the entire contents of each drum through 1:1 splitters until a mass of about 500 g is obtained from each of the primary increments.

8.2.3 Combine the $(N \times n)$ secondary increments constituting the secondary sample and homogenize. Reduce the bulk of the sample by consecutive riffing through 1:1 splitters to obtain the required number of laboratory samples.

9 Sampling report

The sampling report shall include the following particulars:

- a) reference to the appropriate clauses of this International Standard;
- b) any operation not included in this International Standard or which is regarded as optional;
- c) any unusual features noted during sampling or any deviations made from the sampling procedure.
