**ASTM INTERNATIONAL**

**Designation: E 2078 – 00**

# Standard Guide for
# Analytical Data Interchange Protocol for Mass Spectrometric Data[1]

This standard is issued under the fixed designation E 2078; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

## 1. Scope

1.1 This guide covers the implementation of the Mass Spectrometric Data Protocol in analytical software applications. Implementation of this protocol requires:

1.1.1 Specification E 2077, which contains the full set of data definitions. The mass spectrometric data protocol is not based upon any specific implementation; it is designed to be independent of any particular implementation so that implementations can change as technology evolves. The protocol is implemented in categories to speed its acceptance through actual use.

1.1.2 Specification E 2077 contains a full description of the contents of the data communications protocol, including the analytical information categories with data elements and their attributes for most aspects of mass spectrometric tests.

1.2 The analytical information categories are a practical convenience for breaking down the standardization process into smaller, more manageable pieces. It is easier for developers to build consensus and produce working systems based on smaller information sets, without the burden and complexity of the hundreds of data elements contained in all the categories. The categories also assist vendors and end users in using the guide in their computing environments.

1.3 The network common data format (NetCDF) data interchange system is the container used to communicate data between applications in a way that is independent of both computer architectures and end-user applications. In essence, it is a special type of application designed for data interchange.

1.4 The common data language (CDL) template for mass spectrometry is a language specification of the mass spectrometry dataset being interchanged. With the use of the NetCDF utilities, this human-readable template can be used to generate an equivalent binary file and the software subroutine calls needed for input and output of data in analytical applications.

## 3. List of Contents and Use

3.1 *NetCDF Toolkit*—The protocol is an application programming interface (API) layered on top of the public domain NetCDF toolkit. NetCDF is a set of tools that facilitate reading or writing platform-independent, self-describing data files. All data in a NetCDF file is written using the external data representation (XDR). XDR was developed by Sun Microsystems and is used for platform-independent file systems for all workstations and personal computers. Each NetCDF data element is self-describing - it has a name, type, and dimensionality. A NetCDF file contains three parts: a *dimensions* section, which defines the names and size of all dimensions used to describe variables; a *variables* section, which defines the names, data types, dimensionality, and attributes for all variables used in the file; and finally, a *data* section, which contains the actual values assigned to the variables. Attributes are numbers or strings which augment the description of variables or the file as a whole.

3.1.1 For example, a variable "x_axis_ values" might contain an array of numbers representing the abscissa of a two-dimensional data set. It would have a dimension, possibly named "x_axis_size," which would specify the number of abscissa points. The variable might have some descriptive attributes, such as "units" (with a value of " Seconds," perhaps), "scale_factor" (with a value of 1000.0, specifying that all stored abscissa values should be multiplied by 1000.0 to get the actual value), or "long_name" (with value " Time", which might be used to label the abscissa when drawing a plot).

3.1.2 The NetCDF toolkit has been placed in the public domain by the Unidata Program Center, a non-profit software

support organization for the University Corporation for Atmospheric Research. The Unidata Program Center is funded by the National Science Foundation, National Center for Atmospheric Research, and other organizations and provides ongoing development and support of NetCDF and related tools.

3.1.3 The NetCDF version currently supported in this implementation is 2.3.2.

3.2 *Data Structures*—Each of the analytical information class tables in the specification document has a corresponding data structure; however, not every field in each table has a corresponding data element in a structure, and the data structures may have elements that do not appear in any class table. Most of these differences are due to details of the implementation which could not be hidden.

3.2.1 The data structures provide the mapping between the attribute name and data type described in the specification and the field and actual data type in the file. The actual NetCDF dimension, variable, and attribute names are hidden from the API level. These names in fact are irrelevant for application programs; it is the data structure which provides the information interchange between the application and the file.

3.2.2 Each data structure and its mapping to an analytical information class are described in detail later in this guide.

3.2.3 *Application Programming Interface Functions*:

3.2.3.1 The application programming interface provides programmatic access to the contents of the files. Mass spectral data occurs in three forms: global information, which relates to the contents of the entire file, information which describes each part of a multi-component instrument, and information which changes on a scan-by-scan basis for spectra and library entries. API functions are provided for opening a file for reading or writing; closing a file; reading and writing global, per-component instrument, and per-scan spectral and library information; initializing and clearing data structure contents; and a few miscellaneous utility functions. Each of these functions is described in detail in a later section of this guide.

3.2.4 *Enumerated Sets*—Many of the attributes listed in the Analytical Data Interchange Protocol for Mass Spectrometric Data specification have an enumerated set of associated values. The attribute may take only one value from that restricted set. In the implementation, each such attribute is defined as a formal C type, and the allowed values are defined as an enumerated set of that formal type. Each enumerated value is associated with a unique string literal, and it is these string literals, not the enumeration values, which are written to or read from the file. This practice both enforces the use of the proper enumeration values and follows the NetCDF dictum that files be self-describing. If the enumeration values were written instead of the strings, then some lookup mechanism would be required external to the NetCDF file to translate the number into something meaningful.

## 4. Conventions

4.1 The format convention adopted in this guide is as follows:

*(1)* Normal text is presented in this font (Times New Roman).

*(2)* API symbols (functions, formal types, etc.) are presented in **boldface Helvetica font**.

*(3)* Parameters to API functions are presented in *italic Helvetica font*.

*(4)* Example code is presented in normal Helvetica font.

4.2 *Other Conventions*—All indices begin at zero (C convention). In several data structures, a **scan_no** or **inst_no** element must be loaded before reading or writing. This identifies the scan or instrument component number for which data will be read or written. In all cases, scan or instrument component numbers begin at zero.

4.2.1 All date/time stamps are formatted using the ISO standard 8601 format referenced in the specification. An API utility function is provided for conversion between date/time information in numeric form and ISO-8601 string format (see **ms_convert_date()**, below).

## 5. Mass Spectrometric Data Protocol Distribution Kit

5.1 It is intended that potential users of this implementation can obtain a complete NetCDF and API distribution kit from various instrument vendors' Web sites. Information on how to obtain the kit will be posted on the ASTM website (www.astm.org) under Committee E01.25.

5.2 The Analytical Data Interchange Protocol for Mass Spectrometric Data distribution kit contains:

5.2.1 *Software*—NetCDF distribution kit from Unidata (with the modified makefile needed to make the kit compile out of the box).

5.2.2 *NetCDF User's Guide*—supplied by Unidata Program Center.

5.2.3 *Specification E 2077*.

5.2.4 *Guide E 2078*.

## 6. Hardware and Software

6.1 This section describes the hardware and software configurations used for testing. In general, the NetCDF system puts very few requirements on the hardware because most routines are left on disk. Only routines being used at any particular time are kept in memory. Any limitations found were typically those not imposed by NetCDF but ones imposed by the operating system or environment.

6.1.1 *Hardware (Personal Computers)*—The personal computer system hardware originally used for testing was:

6.1.1.1 Intel 80286 processor,

6.1.1.2 640K minimum,

6.1.1.3 Monochrome, EGA, VGA graphics,

6.1.1.4 20 megabyte minimum, 80 megabyte hard-disk is typical, and

6.1.1.5 A mouse (optional).

6.1.1.6 NetCDF works well on AT-class machines and higher. NetCDF does not have the items in 6.1.1.1-6.1.1.5 as requirements. These are just the minimum, base-level systems that were used.

6.1.2 *Software*—NetCDF runs on MS-DOS, OS/2, Macintosh, Windows 95, and Windows NT operating systems for personal computers. NetCDF was originally ported from UNIX to DOS running on an IBM-PS/2 Model 80. It was recently ported to the Macintosh OS. NetCDF is written in the C programming language, and there are FORTRAN jackets available for applications that want to use FORTRAN calls.

The personal computer software originally employed for testing and developing NetCDF applications was:

6.1.2.1 Microsoft DOS V3.3 or above,

6.1.2.2 Microsoft C Compiler V6.0,

6.1.2.3 Microsoft Windows V3.0,

6.1.2.4 Microsoft Windows SDK, and

6.1.2.5 NetCDF Version 2.0.1.

6.1.3 *Workstations and Servers*—NetCDF runs easily on UNIX workstations such as Sun 3, Sun 4, VAXstations, DECstation 3100, VAXstation II running ULTRIX or VMS, and IBM RS/6000. There are no particular hardware requirements for workstation class machines, since all workstations have the minimum hardware outlined for personal computers in 6.1.1.

## 7. Significance and Use

7.1 *General Coding Guidelines*—The NetCDF libraries are supplied to developers as source code. End users receive the libraries in compiled binary form as part of a vendor's application.

7.1.1 Developers setting out to write a program to convert their data files to the Mass Spectrometric Data Protocol should consider using the NetCDF utilities ncgen and ncdump. After developers create the NetCDF file they should use the ncdump program to generate the ASCII representation of the data file, and examine it to ensure the data are being correctly put into the file.

7.2 *Make Files for NetCDF Libraries and Utilities*—In general the compilation is straightforward. The make files were modified after they were received from the Unidata Corporation, because they did not compile the first time on PCs. The changes needed to get the Unidata distribution to run on DOS are (*1*) rename the file MAKEFILE to UNIX.MK, and (*2*) rename MSOFT.MK to MAKEFILE, and then run NMAKE. The default switches in the Unidata distribution use the switches for the floating point coprocessor and Microsoft Windows options.

7.2.1 The protocol kit contains some complete makefile examples for Microsoft C V6.0 running on DOS. The Microsoft C V6.0 compiler manual should be consulted for the exact meaning of the compiler and linker options.

7.2.2 The VMS and SunOS compilation instructions are in directories for those operating systems.

7.3 *NetCDF Library Build Order*—The NetCDF libraries must be built in a specific order. The correct order to build the NetCDF directories is:

```
UTIL
XDR
SRC
NCDUMP
NCGEN
NCTEST
```

7.3.1 The UTIL and XDR makefiles work as distributed using NMAKE with Microsoft C V6.0.

## 8. CDL Template Structure

8.1 A NetCDF template is built from CDL statements and is structured into three sections: (*1*) dimension declarations, (*2*) variable declarations, and (*3*) the data section.

8.2 A few points of clarification about the CDL language are given here to facilitate its understanding. For more in-depth information on CDL, please consult the *NetCDF User's Guide*.

8.2.1 A NetCDF template starts with the word "NetCDF" followed by the dataset name.

8.2.2 CDL comments are indicated by two forward slash characters (//).

8.2.3 Section indicators (dimensions:, variables:, and data:) end with a colon character (:). These are the only tokens that end with a colon character.

8.2.4 Statements within sections end with the semicolon character (;).

8.2.5 Variable names beginning with numbers must be preceded by an underline character (_). Otherwise the ncgen parser will flag an error.

8.2.5.1 Underline characters were chosen for this protocol over hyphen characters, because some compilers may interpret hyphens as subtraction operators. The feature of CDL that allows implicit numerical datatyping of attributes in not being used in the first version of the template. Instead, all floating point attributes are being handled as strings. This forces programmers to explicitly type variables, thereby encouraging more deliberate programming styles. For example:

```
:aia_template_revision = "0.8"; //M12345
:netcdf_revision = "2.0.1"; //M12345
```

Consult the *NetCDF User's Guide* for more complete information on CDL syntax and usage.

8.2.6 Underline characters only can be used as separators between words within variable names, like:

```
aia-template-revision, or aia_template_revision.
```

8.2.7 Numerical data types for single values can be declared implicitly by putting numbers on the right side of an assignment statement, like:

```
peak_number=2; //number of peaks
```

These numerical datatypes can be floating point or integer values, and can be implicitly datatyped as such.

```
:floating_point_attribute = 1.11; //M12345
```

8.2.8 Numerical data types can be declared explicitly by preceding the variable definition by its data type. Datatype assignments can be for either single value variable definitions or for array variable definitions, for example:

```
float detector_maximum_value;
float ordinate_values(point_number);
```

There is also a way to explicitly declare datatypes on the right side of an assignment operator. Please consult the *NetCDF User's Guide* for details.

8.2.9 Metadata are associated with a particular variable by attaching it to that variable with a colon character, for example:

```
ordinate_values:uniform_sampling_flag=" Y";
ordinate_values:autosampler_position=" 1.01";
```

8.2.10 Global metadata can be declared simply by not attaching it to any variable, for example:

```
:aia_template_revision= "0.8"; //M12345
```

8.2.11 String attributes can be as long as needed, and are declared by enclosing the strings in quotation marks, for example:

:retention_unit= "time in seconds";

8.3 *Notes About the Mass Spectrometric Data Protocol Usage of CDL*—Some mandatory indicator codes (M-codes) for data elements such as M1234, M1, etc., are given in some comment fields of the protocol template. These are *not* part of CDL syntax. These refer to whether a given data element is mandatory for particular information categories, for example, M1234 specifies that the data element is mandatory for Categories 1, 2, 3, and 4. These M-codes are also given in the Specification E 2077.

## 9. Other Usage Tips

9.1 *Filename Extensions*—The recommended filename extension is ".cdf," so that the full name for a NetCDF file would be "filename.cdf." This is used so that parsers used to select files can parse filenames based on the ".cdf" extension rather than some other non-standard file extension.

9.2 *Handling of a Missing Variable*—The absence of a variable implies that it is not in the file. For example, if a get operation returns an error condition, this implies that the variable does not exist in that file.

9.3 *Performance Tip For Data Value Access*—The point_number dimension was originally declared as "unlimited"; however, this was changed to a finite value because this change allows getting and putting of an entire array at once. This change is minor and will not affect programs, however, it greatly improves performance. Using point_num as unlimited restricts get/put operations to single values at a time, that is, they are treated as records.

9.4 *Getting Valid Date Time Stamps*—In order to get the correct date-time-stamp values in datasets originating from DOS and OS/2 systems, the environment variable for time zone must be set correctly. The recommended procedure is to set the offset form Greenwich Mean Time (GMT) *at product installation time*. Some examples of how to set the time-zone environment variable are as follows:

9.4.1 The command "DOS-PROMPT>tz pst 8 pdt" sets the time-zone variable to have a GMT offset of Pacific Standard Time (pst), with a value of 8 h offset from GMT, at Pacific Daylight Time (pdt).

9.4.2 The command "DOS-PROMPT>tz est 5 edt" sets the time-zone variable to have a GMT offset of Eastern Standard Time (est), with a value of 5 h offset for GMT, at Eastern Daylight Time (edt).

## 10. Data Structures

10.1 The protocol data structures form the heart of the information interchange. When reading a file, the API loads information from the file into the fields of the data structures. The application program is responsible for preparing the data structures for use by the API functions, for removing the information returned by the API, and for clearing the data structures for subsequent use in another API call. When writing a file, the API extracts information from the data structures and writes it to the file. The application program is again responsible for preparing and loading information into the data structures and then clearing them after the API call.

10.1.1 It is important to emphasize that **the application program is responsible for the data structure contents**. API functions are provided to initialize and clear data structure contents. These functions make several assumptions; in order to ensure proper interaction of the protocol and applications and to avoid memory allocation errors, these rules must be followed:

*(1)* When using API functions to read from a file, **the API allocates memory for character strings and numeric arrays**. It is the applications' responsibility to free this memory (using **free**()) after the data structure contents have been used. Failure to do so will result in a memory leak.

*(2)* When using API functions to write to a file, **the API assumes that the application has allocated memory for character strings and numeric arrays**. The API file writing functions do not free this memory; however, API functions which clear data structure contents assume that any non-**NULL** pointers reference allocated memory, and will free the memory and clear the pointers. It is acceptable to use pointers to statically declared storage, but the application must ensure that pointers to such storage are not passed to the data structure initialization routines.

*(3)* When reading an interchange file, a **NULL** pointer will be returned in character string or numeric array fields for which no data is present in the file.

*(4)* When writing an interchange file, **NULL** pointers may be passed in most cases for character strings or numeric arrays for which no data are present or which are inappropriate or inapplicable. Exceptions are noted in the sections below.

10.2 *Administrative Information Class*— **MS_Admin_Data**. The **MS_Admin_Data** data structure maps the administrative information class attributes and data types. It is only referenced once in code, either when reading from or writing to a file. **MS_Admin_Data** is a typedef. Table 1 describes the data structure fields, formal types, and mapping to administrative information class attributes.

10.2.1 *ms_admin_expt_t: Experiment Type*—The default value is shown in grey. See Table 2.

10.3 *Instrument-ID Information Class*— **MS_Instrument_Data**. Instrument data occurs on a per-component basis (that is, an instrument may be composed of one or more instrument components. The total number of components is defined using the **ms_open_write ()** or is read from the interchange file during **ms_open_read ()** (see below). When writing, the **MS_Instrument_Data** structure is filled with the data for each instrument component in turn, and then is written to the interchange file using successive API calls. When reading, the number of instrument components is returned in the **MS_Admin_Data** structure. Data for each component is returned with successive API calls.

10.3.1 When both reading and writing, the **inst_no** field must be filled with the index number of the component. These index numbers are arbitrary, but must be sequential beginning with zero. Other fields must be filled in by the application when writing, or are filled by the API when reading. The application is responsible for initializing the **MS_Instrument_Data** structure before use, and for clearing its contents between API calls. See Table 3.

## TABLE 1 Data Structure Fields

### MS_Admin_Data

| Type | Field Name | E[A] | M[B] | Specification Attribute |
|------|------------|------|------|------------------------|
| char[C] | dataset_completeness | | x | data set completeness[C] |
| char[C] | ms_template_revision | | x | template revision level[C] |
| char[C] | comments | | | administrative comments |
| char[C] | dataset_origin | | | data set origin |
| char[C] | dataset_owner | | | data set owner |
| char[C] | experiment_title | | | experiment title |
| char[C] | experiment_date_time | | x | experiment date/time stamp |
| (1)[D] | experiment_type | x | | experiment type |
| Char[C] | experiment_x_ref_0 | | | experiment cross-references[E] |
| char[C] | experiment_x_ref_1 | | | experiment cross-references[E] |
| char[C] | experiment_x_ref_2 | | | experiment cross-references[E] |
| char[C] | experiment_x_ref_3 | | | experiment cross-references[E] |
| char[C] | netcdf_date_time | | x | NetCDF file date/time stamp |
| char[C] | netcdf_revision | | x | NetCDF revision level[C] |
| char[C] | operator_name | | | operator name |
| char[C] | source_file_reference | | | source file reference |
| char[C] | source_file_format | | | source file format |
| char[C] | source_file_date_time | | | source file date/time stamp |
| char[C] | external_file_ref_0 | | | external file references[E] |
| char[C] | external_file_ref_1 | | | external file references[E] |
| char[C] | external_file_ref_2 | | | external file references[E] |
| char[C] | external_file_ref_3 | | | external file references[E] |
| char[C] | languages | | x | languages[C] |
| Long | number_times_processed | | | number of times processed |
| Long | number_times_calibrated | | | number of times calibrated |
| char[C] | calibration_history_0 | | | calibration history[E] |
| char[C] | calibration_history_1 | | | calibration history[E] |
| char[C] | calibration_history_2 | | | calibration history[E] |
| char[C] | calibration_history_3 | | | calibration history[E] |
| char[C] | post_expt_program_name | | | post-experiment program name |
| char[C] | pre_expt_program_name | | | pre-experiment program name |
| char[C] | error_log | | | error log |
| Long | number_instrument_components | | | (none)[F] |

[A] The E column indicates that this is an enumerated set field. It is recorded in the interchange file as a string literal, but is represented as an enumerated type in the data structure.

[B] The M column indicates that this is a required field. When reading or writing an interchange file, an error will be generated if a mandatory field is not filled in.

[C] These fields are present in the data structure, but do not need to be filled by the application program when writing an interchange file. The API fills these fields with the appropriate values. However, on reading a file, the contents of these fields are filled with allocated strings, and must be freed by the caller.

[D] (1) Data type is **ms_admin_expt_t**.

[E] These fields are defined in the specification as "string array" types. For convenience of the implementation and to conserve space in the interchange file, they are defined as separate strings here.

[F] The number of instrument components is returned in this field *only* when *reading* an interchange file. It is not used when writing files.

## TABLE 2 Experiment Type

### ms_admin_expt_t

| Value | String literal | Specification description |
|-------|----------------|---------------------------|
| expt_centroid | Centroided Mass Spectrum | centroided mass spectrum |
| expt_continuum | Continuum Mass Spectrum | continuum mass spectrum |
| expt_library | Library Mass Spectrum | library mass spectrum |

10.4 *Sample Description Information Class—* **MS_Sample_Data**. The **MS_Sample_Data** structure occurs once per interchange file. See Table 4.

10.4.1 *ms_sample_state_t:—sample state*. See Table 5.

10.5 *Test Method Information Class—***MS_Test_Data**. The **MS_Test_Data** structure occurs once per interchange

## TABLE 3 MS_Instrument_Data

NOTE 1—There are no enumerated sets associated with **MS_Instrument_Data**.

NOTE 2—All string fields in this structure are restricted to 32 characters (including terminal NULL).

| Type | Field Name | E | M | Specification Attribute |
|------|------------|---|---|------------------------|
| Long | inst_no | | x | instrument component number |
| char[A] | name | | | instrument component name |
| char[A] | id | | | instrument component id |
| char[A] | manufacturer | | | instrument component manufacturer |
| char[A] | model_number | | | instrument component model number |
| char[A] | serial_number | | | instrument component serial number |
| char[A] | comments | | | instrument component id comments |
| char[A] | software_version | | | instrument component software version |
| char[A] | firmware_version | | | instrument component firmware version |
| char[A] | operating_system | | | operating system revision |
| char[A] | application_software | | | application software revision |

[A] These fields are present in the data structure, but do not need to be filled by the application program when writing an interchange file. The API fills these fields with the appropriate values. However, on reading a file, the contents of these fields are filled with allocated strings, and must be freed by the caller.

## TABLE 4 MS_Sample_Data

| Type | Field Name | E | M | Specification Attribute |
|------|------------|---|---|------------------------|
| char[A] | owner | | | sample owner |
| char[A] | receipt_date_time | | | sample receipt date/time stamp |
| char[A] | internal_id | | | internal sample id |
| char[A] | external_id | | | external sample id |
| char[A] | procedure_name | | | sampling procedure name |
| char[A] | prep_procedure | | | sample preparation procedure |
| (1)[B] | state | x | | sample state |
| char[A] | matrix | | | sample matrix |
| char[A] | storage | | | sample storage information |
| char[A] | disposal | | | sample disposal information |
| char[A] | history | | | sample history |
| char[A] | prep_comments | | | sample preparation comments |
| char[A] | comments | | | sample id comments |
| char[A] | manual_handling | | | manual handling precautions |

[A] These fields are present in the data structure, but do not need to be filled by the application program when writing an interchange file. The API fills these fields with the appropriate values. However, on reading a file, the contents of these fields are filled with allocated strings, and must be freed by the caller.

[B] Data type is ms_sample_state_t

## TABLE 5 ms_sample_state_t

| Value | String Literal | Specification Description |
|-------|----------------|---------------------------|
| state_solid | Solid | solid |
| state_liquid | Liquid | liquid |
| state_gas | Gas | gas |
| state_supercrit | Supercritical Fluid | supercritical fluid |
| state_plasma | Plasma | plasma |
| state_other | Other State | other state |

file. Depending on the specifics of the experiment which generated the data set, many fields will most likely be inappropriate or inapplicable. Only those fields which are appropriate need be changed from the default values set during initialization, and only those which have non-default values will be read from or written to the interchange file. See Table 6.

**TABLE 6 MS_Test_Data**

| Type | Field name | E | M | Specification Attribute |
|---|---|---|---|---|
| ms_test_separation_t | separation_type | x | | separation experiment type |
| ms_test_inlet_t | ms_inlet | x | | mass spectrometer inlet |
| Float | ms_inlet_temperature | | | mass spectrometer inlet temperature |
| ms_test_ioniz_t | ionization_mode | x | | ionization mode |
| ms_test_polarity_t | ionization_polarity | x | | ionization polarity |
| Float | electron_energy | | | electron energy |
| Float | laser_wavelength | | | laser wavelength |
| char[A] | reagent_gas | | | reagent gas |
| Float | reagent_gas_pressure | | | reagent gas pressure |
| char[A] | fab_type | | | FAB type |
| char[A] | fab_matrix | | | FAB matrix |
| Float | source_temperature | | | source temperature |
| Float | filament_current | | | filament current |
| Float | emission_current | | | emission current |
| Float | accelerating_potential | | | accelerating potential |
| ms_test_detector_t | detector_type | x | | detector type |
| Float | detector_potential | | | detector potential |
| Float | detector_entrance_potential | | | detector entrance potential |
| ms_test_res_t | resolution_type | x | | resolution type |
| char[A] | resolution_method | | | resolution method |
| ms_test_function_t | scan_function | x | | scan function |
| ms_test_direction_t | scan_direction | x | | scan direction |
| ms_test_law_t | scan_law | x | | scan law |
| Float | scan_time | | | scan time |
| char[A] | mass_calibration_file | | | mass calibration file name |
| char[A] | external_reference_file | | | external reference file name |
| char[A] | internal_reference_file | | | internal reference file name |
| char[A] | comments | | | instrument parameter comments |

[A] These fields are present in the data structure, but do not need to be filled by the application program when writing an interchange file. The API fills these fields with the appropriate values. However, on reading a file, the contents of these fields are filled with allocated strings, and must be freed by the caller.

10.5.1 *ms_test_separation_t:—separation method*. See Table 7.

**TABLE 7 ms_test_separation_t**

| Value | String Literal | Specification Description |
|---|---|---|
| separation_glc | Gas-Liquid Chromatography | gas-liquid chromatography |
| separation_gsc | Gas-Solid Chromatography | gas-solid chromatography |
| separation_nplc | Normal Phase Liquid Chromatography | normal phase liquid chromatography |
| separation_rplc | Reverse Phase Liquid Chromatography | reverse phase liquid chromatography |
| separation_ielc | Ion Exchange Liquid Chromatography | ion exchange liquid chromatography |
| separation_selc | Size Exclusion Liquid Chromatography | size exclusion liquid chromatography |
| separation_iplc | Ion Pair Liquid Chromatography | ion pair liquid chromatography |
| separation_olc | Other Liquid Chromatography | other liquid chromatography |
| separation_sfc | Supercritical Fluid Chromatography | supercritical fluid chromatography |
| separation_tlc | Thin Layer Chromatography | thin layer chromatography |
| separation_fff | Field Flow Fractionation | field flow fractionation |
| separation_cze | Capillary Zone Electrophoresis | capillary zone electrophoresis |
| separation_other | Other Chromatography | other chromatography |
| separation_none | No Chromatography | no chromatography |

10.5.2 *ms_test_inlet_t:—mass spectrometer inlet*. See Table 8.

10.5.3 *ms_test_ioniz_t:—ionization method*. See Table 9.

10.5.4 *ms_test_polarity_t:—ionization polarity*. See Table 10.

10.5.5 *ms_test_detector_t:—detector type*. See Table 11.

10.5.6 *ms_test_res_t:—resolution type*. See Table 12.

10.5.7 *ms_test_function_t:—scan function*. See Table 13.

10.5.8 *ms_test_direction_t:—scan direction*. See Table 14.

10.5.9 *ms_test_law_t:—scan law*. See Table 15.

10.6 *Raw Data Information Classes*:

10.6.1 *Raw Data Global Information Class—* **MS_Raw_Data_Global**. The **MS_Raw_Data_Global** structure occurs once per interchange file. The only required field is **nscans**, the number of spectral scans or library spectra recorded in the set. See Table 16.

10.6.1.1 *ms_data_mass_t:—mass axis units*. See Table 17.

10.6.1.2 *ms_data_time_t:—time axis units*. See Table 18.

10.6.1.3 *ms_data_intensity_t:—intensity axis units*. See Table 19.

10.6.1.4 *ms_data_format_t:—data format*. See Table 20.

10.7 *Raw Data Per-Scan Information Class—* **MS_Raw_Per_Scan**. A copy of this structure is completed once for each scan in the interchange file. When reading or writing, the **scan_no** field is used to indicate the index number of the scan (beginning at zero) to be read or written, respectively. Scans can be read or written in ascending or descending order; however, an error will occur if a scan number outside the range of one to (**nscans** (see **MS_Raw_Data_Global**, above) is specified.

10.7.1 There are no enumerated types in the **MS_Raw_Per_Scan** data structure. See Table 21.

10.8 *Library Data Per-Scan Information Class—* **MS_Raw_Library**—This structure occurs once per spectrum, but only for experiment type **expt_library**. For other experiment types, this structure is not used. An error will result when trying to read or write library information for experiment types other than **expt_library**. As in **MS_Raw_Per_Scan**, the **scan_no** variable must be set to the desired scan index before

**TABLE 8 ms_test_inlet_t**

| Value | String Literal | Specification Description |
|---|---|---|
| inlet_membrane | Membrane Separator | membrane separator |
| inlet_capillary | Capillary Direct | capillary direct |

| direction_down | Down | down |
| direction_other | Other Direction | other direction |

#### TABLE 15 ms_test_law_t

| Value | String Literal | Specification Description |
|---|---|---|
| law_linear | Linear | linear |
| law_exponential | Exponential | exponential |
| law_quadratic | Quadratic | quadratic |
| law_other | Other Law | other law |

10.8.1 *Size Restrictions on other Library String Fields (including terminal NULL)*:

| | |
|---|---|
| **entry_id** | 32 bytes |
| **source_data_file_reference** | 32 bytes |
| **chemical_formula** | 64 bytes |
| **wiswesser** | 128 bytes |
| **smiles** | 255 bytes |
| **other_structure** | 128 bytes |
| **retention_reference_name** | 128 bytes |
| **other_info** | 255 bytes |

10.9 *Raw Data Per-Scan-Group Information Class—* **MS_Raw_Per_Group**. This structure is only used when the scan function is selected ion detection (function_sid), and occurs once per scan group. The group_no variable must be set to the desired group index before both reading and writing. An out-of-range index results in an error.

There are no enumerated types. See Table 23.

**11. Application Programming Interface**

11.1 There are a number of commonly used functions available in the application programming interface. These are grouped as follows:

11.1.1 Opening and closing interchange files,

11.1.2 Reading and writing global data,

11.1.3 Reading and writing per-component instrument data,

11.1.4 Reading and writing per-scan raw and library data,

11.1.5 Data structure initialization and clearing, and

#### TABLE 16  MS_Raw_Data_Global

| Type | Field name | E | M | Specification Attribute |
|---|---|---|---|---|
| Long | nscans | | x | number of scans |
| Long | starting_scan_no | | | starting scan number |
| Int | has_masses | | | (none)[A] |
| Int | has_times | | | (none)[A] |
| Double | mass_factor | | | mass axis scale factor[B] |
| Double | time_factor | | | time axis scale factor[B] |
| Double | intensity_factor | | | intensity axis scale factor[B] |
| Double | intensity_offset | | | intensity axis offset[C] |
| ms_data_mass_t | mass_units | | x | mass axis units |
| ms_data_time_t | time_units | | x | time axis units |
| ms_data_intensity_t | intensity_units | | x | intensity axis units |
| ms_data_intensity_t | total_intensity_units | | x | total intensity units |
| ms_data_format_t | mass_format | | x | mass axis data format |
| ms_data_format_t | time_format | | x | time axis data format |
| ms_data_format_t | intensity_format | | x | intensity axis data format |
| char[A] | mass_label | | | mass axis label |
| char[A] | time_label | | | time axis label |
| char[A] | intensity_label | | | intensity axis label |
| Double | mass_axis_global_min | | | mass axis global range[D] |
| Double | mass_axis_global_max | | | mass axis global range[D] |
| Double | time_axis_global_min | | | time axis global range[D] |
| Double | time_axis_global_max | | | time axis global range[D] |
| Double | intensity_axis_global_min | | | intensity axis global range[D] |
| Double | intensity_axis_global_min | | | intensity axis global range[D] |
| Double | calibrated_mass_min | | | calibrated mass range[D] |
| Double | calibrated_mass_max | | | calibrated mass range[D] |
| Double | run_time | | | actual run time |
| Double | delay_time | | | actual delay time |
| Short | uniform_flag | | | uniform sampling flag |
| char[A] | Comments | | | raw data global comments |

[A] These fields are used only when reading an interchange file, and indicate the presence of mass or time data, or both, in the interchange file. This allows applications to set up in advance to receive mass or time data or both.

[B] Scale factors default to 1.0. Scale factors are used as follows: When reading data arrays, the values returned in the arrays should each be multiplied by the respective scale factor to obtain the true values. When writing data arrays, the scale factor represents the divisor applied to the true values to obtain the values recorded in the interchange file. In either case, the numbers present in the mass, time, and intensity values arrays (see **MS_Raw_Per_Scan** data structure, below) represent the scaled, not the true values. The application is responsible for performing the appropriate scaling when reading or writing.

[C] The intensity axis offset defaults to 0.0. There are no offsets for the time or mass axes. When reading, the offset should be added to the recorded intensity values (**after scaling**) to obtain the true intensity values. When writing, the offset should be subtracted from the true values (**before scaling**).

[D] These fields are defined in the specification as ranges; for convenience of implementation, they are split into separate variables for minimum and maximum values.

#### TABLE 17  ms_data_mass_t

| Value | String Literal | Specification Description |
|---|---|---|
| mass_m_z | M/Z | m/z |
| mass_arbitrary | Arbitrary Mass Units | arbitrary units |
| mass_other | Other Mass Units | other units |

11.1.6 Utility routines.

11.2 There are some additional API functions of lesser importance; these are not required for normal use of the protocol, but are described for completeness.

11.2.1 Note that, the header file "ms10.h" referenced below existed in earlier, preliminary, non-ASTM implementations

#### TABLE 18  ms_data_time_t

| Value | String Literal | Specification Description |
|---|---|---|
| time_seconds | Seconds | seconds |
| time_arbitrary | Arbitrary Time Units | arbitrary units |
| time_other | Other Time Units | other units |

#### TABLE 19  ms_data_intensity_t

| Value | String Literal | Specification Description |
|---|---|---|
| intensity_counts | Total Counts | total counts |
| intensity_cps | Counts Per Second | counts per second |
| intensity_volts | Volts | volts |
| intensity_current | Current | current |
| intensity_arbitrary | Arbitrary Intensity Units | arbitrary units |
| intensity_other | Other Intensity | other units |

#### TABLE 20  ms_data_format_t

| Value | String Literal | Specification Description |
|---|---|---|
| data_short | Short | short (16-bit signed integer)[A] |
| data_long | Long | long (32-bit signed integer)[B] |
| data_float | Float | float (32-bit floating point) |
| data_double | Double | double (64-bit floating point) |

[A] Default for mass and time data.
[B] Default for intensity data.

also named "ms11.h" and subsequently "ms12.h". It was finally named, perhaps confusingly, "ms10.h" to indicate a version "1.0" for the originally intended AIA standard.

11.3 *File Open and Close*—Interchange files are opened either for reading or writing. On most operating systems, opening a file for writing will destroy any existing file of the same name (on VMS, a new version is created). A file opened for reading must already exist. There are two file open API calls, one for read access and one for write access. These functions do much more than open the file; they read in or write out NetCDF dimension names and sizes and variable names and dimensionalities, respectively, and place the file in the appropriate mode for further operations.

11.3.1 *ms_open_read*—*open an interchange file for reading:*

**Syntax:**
    #include        "ms10.h"
    **int ms_open_read ( char *** *filename* )

**Description:**

The **ms_open_read** routine opens the interchange file named by *filename* and associates a file identifier with it. Any dimensions and variables defined in the file are read into internal API data structures. The file must exist, be readable, and be an interchange format file.

**Return values:**

If successful, the **ms_open_read** routine returns a non-negative **int** file identifier for use in subsequent API calls. On error, the routine returns the error code **MS_ERROR** (defined in ms10.h).

## TABLE 21 MS_Raw_Per_Scan

Note 1—Mass, time, and intensity arrays are declared as **void \***. In use, however, they are declared as arrays of type appropriate to the mass, time, and intensity data format (see **MS_Raw_Data_Global**, above), and simply cast to **void \*** in the data structure. On writing, the API extracts the data and casts it back to the appropriate types before writing to the file. On reading, the API creates new arrays of the correct types, reads data into them, then casts to **void \*** before returning to the application.

| Type | Field name | E | M | Specification Attribute |
|---|---|---|---|---|
| Long | scan_no | | x | scan number |
| Long | actual_scan_no | | x | actual scan number |
| Long | points | | x | number of points |
| void[A] | masses | | x | mass axis values[A] |
| void[A] | times | | x | time axis values[A] |
| void[A] | intensities | | x | intensity axis values[B] |
| Long | flags | | x | number of flags |
| long[A] | flag_peaks | | | flagged peaks[C] |
| short[A] | flag_values | | | flag values[C] |
| Double | total_intensity | | | total intensity |
| Double | a_d_rate | | | a/d sampling rate |
| Short | a_d_coadditions | | | a/d coaddition factor |
| Double | scan_acq_time | | | scan acquisition time |
| Double | scan_duration | | | scan duration |
| Double | mass_range[2] | | | mass scan range |
| Double | time_range[2] | | | time scan range |
| Double | inter_scan_time | | | inter-scan time |
| Double | resolution | | | resolution |

[A] On reading, one of these pointers may be returned as **NULL** if the respective data is not found in the file. On writing, if one of these types is not present **for all scans in the file**, a **NULL** pointer may be passed in for the missing type. **Either mass values, time values, or both must be present**. All mass/intensity or time/intensity data occur as matched pairs; mass/time/intensity data occur as matched triplets. Therefore, if mass/time/intensity values are present for one scan, they must be present for all scans. Mass data is an array of **mass_format type**; time data is an array of **time_format** type. **All datum values, whether mass or time, are recorded in ascending order.**

On writing, if a scan has no data (**points = 0**), then **NULL** pointers may be passed for **masses, times, intensities, flag_peaks**, and **flag_values**. On reading, **NULL** pointers will be returned.

[B] Intensity axis values are an array of **intensity_format** type. There must be a one-to-one match between intensity datum points and the corresponding mass, time or mass/time point.

[C] On writing, these pointers may be passed as **NULL** if **flags = 0**. On reading, **NULL** pointers will be returned if there are no flagged peaks.

On either reading or writing, the datum values in the **flag_peaks** array correspond to the index of the peak in the mass or time values array (starting at zero). For example, a scan with ten masses, the first, fifth, and sixth of which are flagged, would have a **flag_peaks** array containing the values (0, 4, 5).

**Flag_values** datum points are each the logical OR of individual flag values, and apply to the corresponding datum point in the **flag_peaks** array.

11.3.2 *ms_open_write*—*open an interchange file for writing:*

**Syntax:**

#include "ms10.h"

**int ms_open_write ( char \*** *filename* **, ms_admin_expt_t** *expt_type*, **long** *nscans*, **long** *ninst*, **ms_data_format_t** *mass_fmt*, **ms_data_format_t** *time_fmt*, **ms_data_format_t** *inty_fmt*, **int** *has_masses*, **int** *has_times*)

**Description:**

The **ms_open_write** routine creates and opens the interchange file specified by *filename* and associates a file identifier with it. The NetCDF dimension and variable definitions are written to the file, then the file is placed in data recording

## TABLE 22 MS_Raw_Library

| Type | Field name | E | M | Specification Attribute |
|---|---|---|---|---|
| Long | scan_no | | x | (none) |
| char[A] | entry_name | | x | entry name[A] |
| char[A] | entry_id | | | entry id |
| Long | entry_number | | | original entry number |
| char[A] | source_data_file_reference | | | source data file reference |
| char[A] | cas_name | | | CAS name[A] |
| char[A] | other_name_0 | | | other names[A,B] |
| char[A] | other_name_1 | | | other names[A,B] |
| char[A] | other_name_2 | | | other names[A,B] |
| char[A] | other_name_3 | | | other names[A,B] |
| Long | cas_number | | | CAS number |
| char[A] | formula | | | chemical formula |
| char[A] | wiswesser | | | Wiswesser notation |
| char[A] | smiles | | | SMILES notation |
| char[A] | molfile_reference | | | MOL file reference name |
| char[A] | other_structure | | | other structure notation |
| Double | retention_index | | | retention index |
| char[A] | retention_type | | | retention index type |
| Double | absolute_retention | | | absolute retention time |
| Double | relative_retention | | | relative retention |
| char[A] | retention_reference | | | retention reference name |
| Long | retention_cas | | | retention reference CAS number |
| Float | mp | | | melting point |
| Float | bp | | | boiling point |
| Double | chemical_mass | | | chemical mass |
| Long | nominal_mass | | | nominal mass |
| Double | accurate_mass | | | accurate mass |
| char[A] | other_info | | | other information |

[A]There are a maximum of six names (entry, CAS, and four other) permitted per entry. **A limit of 255 characters per name is imposed.**

[B]These fields are defined as a string array in the specification document; they are implemented are separate string variables here for convenience.

## TABLE 23 MS_Raw_Per_Group

| Type | Field name | E | M | Specification Attribute |
|---|---|---|---|---|
| Long | group_no | | x | (none) |
| Long | mass_count | | x | number of masses in group |
| Long | starting_scan | | x | starting scan number |
| double[A] | masses | | x | group masses[A] |
| double[A] | sampling_times | | | sampling times[A] |
| double[A] | delay_times | | | delay times[A] |

[A]These are parallel arrays; that is, for every mass, there is a corresponding sampling time and delay time entry. The delay time for the last mass in the group may be set to zero (since there is no next mass).

**Important**—The API assumes that these three arrays have constant dimensionality equal to the **maximum number** of masses in any group. (See **ms_write_group_global ()** and **ms_read_group_global ()**, below). On input or output, the API fills unused values with the floating point default. On file write, these arrays are assumed to be defined (and owned) by the caller. On file read, the arrays will be dynamically allocated by the API. It is the caller's responsibility to free this storage after use.

mode. The application must have the file system permissions necessary to create and write to the file.

The other arguments are:

| | |
|---|---|
| *expt_type* | the enumerated set value which specifies the experiment type. |
| *nscans* | number of scans to be recorded |
| *ninst* | number of instrument components (if zero, instrument variables will not be defined in the file) |
| *mass_fmt* | the enumerated set value which specifies the mass values type |
| *time_fmt* | the enumerated set value which specifies the time values type |
| *inty_fmt* | the enumerated set value which specifies the intensity values type |
| *has_masses* | if non-zero, specifies that mass data will be recorded |

| has_times | if non-zero, specifies that time data will be recorded; one of these two arguments must be non-zero. |
|---|---|

**Return values:**

If successful, the **ms_open_write** routine returns a non-negative **int** file identifier for use in subsequent API calls. On error, the routine returns the error code **MS_ERROR**.

11.3.3 *ms_close—close an open file:*

**Syntax:**

```
#include          "ms10.h"
void ms_close ( int file_id )
```

**Description:**

The **ms_close** routine closes the previously opened interchange file associated with the file identifier *file_id* and disassociates the file identifier. No additional API calls may be made using the file identifier after this call completes.

**Return values:**

No values are returned. Any errors are ignored.

11.4 *Reading and Writing Global Data*—Global data occurs once per interchange file. Data structures which contain global data are: **MS_Admin_Data, MS_Sample_Data, MS_Test_Data, and MS_Raw_Data_Global**. In the implementation, most of the fields in these data structures are written as NetCDF dimensions or global attributes.

11.4.1 *ms_read_global—read global information:*

**Syntax:**

```
#include          "ms10.h"
int ms_read_global ( int file_id , MS_Admin_Data *
admin_data , MS_Sample_Data* sample_data , MS_Test_Data * test_data, MS_Raw_Data_Global * raw_data )
```

**Description:**

Reads global information from the interchange file associated with *file_id*. The file must have been opened using **ms_open_read**. Pointers to the data structures must be non-**NULL** and reference valid structures. On return, the data structure fields will be filled with values read from the interchange file. See the discussion of data structure initialization and clearing, below.

**Return values:**

If the call is successful, the code **MS_NO_ERROR** is returned. On an error, the code **MS_ERROR** is returned. An error will occur if the file identifier is invalid, any data structure pointer is **NULL**, memory allocation fails to allocate storage for input data, or on an internal NetCDF error.

11.4.2 *ms_write_global—write global information:*

**Syntax:**

```
#include          "ms10.h"
int ms_write_global ( int file_id, MS_Admin_Data *
admin_data, MS_Sample_Data * sample_data, MS_Test_Data * test_data, MS_Raw_Data_Global * raw_data
```

)

**Description:**

Writes global information to the interchange file associated with *file_id*. The file must have been opened using **ms_open_write**. Pointers to the data structures must be non-**NULL** and reference valid structures. Values are extracted from the data structure fields and are written to the interchange file. It is important to initialize the data structures (using **ms_init_global ()** ) before filling them. Any data structure element which has a NULL value will not be written. See the discussion of data structure initialization and clearing, below.

**Return values:**

If the call is successful, the code MS_NO_ERROR is returned. On an error, the code MS_ERROR is returned. An error will occur if the file identifier is invalid, any data structure pointer is NULL, or on an internal NetCDF error.

11.4.3 *ms_read_group_global—read group global information*

**Syntax:**

```
#include          "ms10.h"
int ms_read_group_global ( int file_id, long * number_of_groups, long * maximum_number_of_masses_in_group)
```

**Description:**

The **ms_read_group_global** function retrieves global scan group information from the interchange file associated with *file_id*. The file must have been opened using **ms_open_read**. Scan group information is stored only for experiments for which the scan function is **function_sid**. If the scan function for the file is not **function_sid** or no scan group data has been recorded in the file, zeros will be stored in the locations pointed to by *number_of_groups* and *maximum_number_of_masses_in_group*.

**Return values:**

If the call is successful, the code MS_NO_ERROR is returned. On an error, the code MS_NO_ERROR is returned. An error will occur if the file identifier is invalid, any data structure pointer is **NULL**, or on an internal NetCDF error.

11.4.4 *ms_write_group_global—write group global information.*

**Syntax:**

```
#include          "ms10.h"
int ms_write_group_global ( int file_id, long number_of_groups, long maximum_number_of_masses_in_group )
```

**Description:**

The **ms_write_group_global** function defines global scan group information to the interchange file associated with *file_id*. The file must have been opened using **ms_open_write**. Scan group information is stored **only** for experiments for which the scan function is **function_sid**. Scan group data
