About the IEC

The International Electrotechnical Commission (IEC) is the leading global organization that prepares and publishes International Standards for all electrical, electronic and related technologies.

About the IEEE

IEEE is the world's largest professional association dedicated to advancing technological innovation and excellence for the benefit of humanity. IEEE and its members inspire a global community through its highly cited publications, conferences, technology standards, and professional and educational activities.

About IEC/IEEE publications

The technical content of IEC/IEEE publications is kept under constant review by the IEC and IEEE. Please make sure that you have the latest edition, a corrigendum or an amendment might have been published.

IEC Catalogue - webstore.iec.ch/catalogue

The stand-alone application for consulting the entire bibliographical information on IEC International Standards, Technical Specifications, Technical Reports and other documents. Available for PC, Mac OS, Android Tablets and iPad.

IEC publications search - www.iec.ch/searchpub

The advanced search enables to find IEC publications by a variety of criteria (reference number, text, technical committee,...). It also gives information on projects, replaced and withdrawn publications.

IEC Just Published - webstore.iec.ch/justpublished

Stay up to date on all new IEC publications. Just Published details all new publications released. Available online and also once a month by email.

Electropedia - www.electropedia.org

The world's leading online dictionary of electronic and electrical terms containing 20 000 terms and definitions in English and French, with equivalent terms in 16 additional languages. Also known as the International Electrotechnical Vocabulary (IEV) online.

IEC Glossary - std.iec.ch/glossary

65 000 electrotechnical terminology entries in English and French extracted from the Terms and Definitions clause of IEC publications issued since 2002. Some entries have been collected from earlier publications of IEC TC 37, 77, 86 and CISPR.

INTERNATIONAL ELECTROTECHNICAL COMMISSION

DETERMINING THE PEAK SPATIAL-AVERAGE SPECIFIC ABSORPTION RATE (SAR) IN THE HUMAN BODY FROM WIRELESS COMMUNICATIONS DEVICES, 30 MHz TO 6 GHz –

Part 3: Specific requirements for using the finite difference time domain (FDTD) method for SAR calculations of mobile phones

FOREWORD

- 1) The International Electrotechnical Commission (IEC) is a worldwide organization for standardization comprising all national electrotechnical committees (IEC National Committees). The object of IEC is to promote international co-operation on all questions concerning standardization in the electrical and electronic fields. To this end and in addition to other activities, IEC publishes International Standards, Technical Specifications, Technical Reports, Publicly Available Specifications (PAS) and Guides (hereafter referred to as "IEC Publication(s)"). Their preparation is entrusted to technical committees; any IEC National Committee interested in the subject dealt with may participate in this preparatory work. International, governmental and non-governmental organizations liaising with the IEC also participate in this preparation.

IEEE Standards documents are developed within IEEE Societies and Standards Coordinating Committees of the IEEE Standards Association (IEEE-SA) Standards Board. IEEE develops its standards through a consensus development process, approved by the American National Standards Institute, which brings together volunteers representing varied viewpoints and interests to achieve the final product. Volunteers are not necessarily members of IEEE and serve without compensation. While IEEE administers the process and establishes rules to promote fairness in the consensus development process, IEEE does not independently evaluate, test, or verify the accuracy of any of the information contained in its standards. Use of IEEE Standards documents is wholly voluntary. *IEEE documents are made available for use subject to important notices and legal disclaimers (see <http://standards.ieee.org/IPR/disclaimers.html> for more information).*

IEC collaborates closely with IEEE in accordance with conditions determined by agreement between the two organizations. This Dual Logo International Standard was jointly developed by the IEC and IEEE under the terms of that agreement.

- 2) The formal decisions of IEC on technical matters express, as nearly as possible, an international consensus of opinion on the relevant subjects since each technical committee has representation from all interested IEC National Committees. The formal decisions of IEEE on technical matters, once consensus within IEEE Societies and Standards Coordinating Committees has been reached, is determined by a balanced ballot of materially interested parties who indicate interest in reviewing the proposed standard. Final approval of the IEEE standards document is given by the IEEE Standards Association (IEEE-SA) Standards Board.
- 3) IEC/IEEE Publications have the form of recommendations for international use and are accepted by IEC National Committees/IEEE Societies in that sense. While all reasonable efforts are made to ensure that the technical content of IEC/IEEE Publications is accurate, IEC or IEEE cannot be held responsible for the way in which they are used or for any misinterpretation by any end user.
- 4) In order to promote international uniformity, IEC National Committees undertake to apply IEC Publications (including IEC/IEEE Publications) transparently to the maximum extent possible in their national and regional publications. Any divergence between any IEC/IEEE Publication and the corresponding national or regional publication shall be clearly indicated in the latter.
- 5) IEC and IEEE do not provide any attestation of conformity. Independent certification bodies provide conformity assessment services and, in some areas, access to IEC marks of conformity. IEC and IEEE are not responsible for any services carried out by independent certification bodies.
- 6) All users should ensure that they have the latest edition of this publication.
- 7) No liability shall attach to IEC or IEEE or their directors, employees, servants or agents including individual experts and members of technical committees and IEC National Committees, or volunteers of IEEE Societies and the Standards Coordinating Committees of the IEEE Standards Association (IEEE-SA) Standards Board, for any personal injury, property damage or other damage of any nature whatsoever, whether direct or indirect, or for costs (including legal fees) and expenses arising out of the publication, use of, or reliance upon, this IEC/IEEE Publication or any other IEC or IEEE Publications.
- 8) Attention is drawn to the normative references cited in this publication. Use of the referenced publications is indispensable for the correct application of this publication.

9) Attention is drawn to the possibility that implementation of this IEC/IEEE Publication may require use of material covered by patent rights. By publication of this standard, no position is taken with respect to the existence or validity of any patent rights in connection therewith. IEC or IEEE shall not be held responsible for identifying Essential Patent Claims for which a license may be required, for conducting inquiries into the legal validity or scope of Patent Claims or determining whether any licensing terms or conditions provided in connection with submission of a Letter of Assurance, if any, or in any licensing agreements are reasonable or non-discriminatory. Users of this standard are expressly advised that determination of the validity of any patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

International Standard IEC/IEEE 62704-3 has been prepared by IEC technical committee 106: Methods for the assessment of electric, magnetic, and electromagnetic fields associated with human exposure, in cooperation with International Committee on Electromagnetic Safety of the IEEE Standards Association¹, under the IEC/IEEE Dual Logo Agreement between IEC and IEEE.

This publication is published as an IEC/IEEE Dual Logo standard.

The text of this standard is based on the following IEC documents:

FDIS	Report on voting
106/404/FDIS	106/414/RVD

Full information on the voting for the approval of this standard can be found in the report on voting indicated in the above table.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

INTRODUCTION

The increasing complexity of assessing product compliance with exposure standards according to specific absorption rate (SAR) limits calls for new compliance or pre-compliance techniques. Currently standardized experimental SAR compliance assessments of wireless communication devices are time-consuming and costly. Computational techniques have reached a level of maturity which allows their use in the pre-compliance assessments of wireless communication devices such as mobile phones. For example, pre-compliance testing is important for mobile phone manufacturers in their product development phase where this document may be applied. The benefits to the users and manufacturers include standardized and accepted protocols, validation techniques, benchmark results, reporting format and means for estimating the overall uncertainty in order to produce valid, repeatable, and reproducible data.

The results obtained by following the protocols specified in this document represent a conservative estimate of the peak spatial-average SAR induced in the standard human body models due to mobile phones. The protocols set forth herein produce results subject to modelling, simulations and other uncertainties that are defined in this document.

It is not the intent of this document to provide a result representative of the absolute maximum SAR value possible under every conceivable combination of human body and mobile phone usage. The following items are described in detail: simulation concepts, simulation techniques, finite difference time domain (FDTD) numerical method, benchmark results, standardized numerical models of the human body. Procedures for validating the numerical tools used for SAR simulations and assessing the SAR simulation uncertainties are provided. This document is intended primarily for use by engineers and other specialists who are familiar with electromagnetic (EM) theory, numerical methods, and, in particular, FDTD techniques. This document does not recommend specific SAR limit values since these are found in other documents.

DETERMINING THE PEAK SPATIAL-AVERAGE SPECIFIC ABSORPTION RATE (SAR) IN THE HUMAN BODY FROM WIRELESS COMMUNICATIONS DEVICES, 30 MHz TO 6 GHz –

Part 3: Specific requirements for using the finite difference time domain (FDTD) method for SAR calculations of mobile phones

1 Scope

This part of IEC/IEEE 62704 defines the concepts, techniques, benchmark phone models, validation procedures, uncertainties and limitations of the finite difference time domain (FDTD) technique when used for determining the peak spatial-average specific absorption rate (SAR) in standardized head and body phantoms exposed to the electromagnetic fields generated by wireless communication devices, in particular pre-compliance assessment of mobile phones, in the frequency range from 30 MHz to 6 GHz. It recommends and provides guidance on the numerical modelling of mobile phones and benchmark results to verify the general approach for the numerical simulations of such devices. It defines acceptable modelling requirements, guidance on meshing and test positions of the mobile phone and the phantom models. This document does not recommend specific SAR limits since these are found in other documents, e.g. IEEE C95.1-2005[1]² and ICNIRP[2].

PEC	perfect electric conductor
PML	perfectly matched layers
RF	radio frequency
SAM	specific anthropomorphic mannequin
SAR	specific absorption rate
SAT	standard ACIS text
UMTS	universal mobile telecommunication system

5 Simulation procedure

5.1 General

Clause 5 presents the steps that shall be followed to compute SAR from a mobile phone placed against a head or a body phantom. The procedure requires voxel models derived from the CAD data files of the DUT and of either the SAM head phantom or the body phantom.

5.2 General considerations

The practical considerations for the application of the FDTD method are provided in Annex C of IEC/IEEE 62704-1:2017. Since the standard FDTD method relies on the Cartesian Yee cell, stair casing of curved surfaces is a problem that needs special consideration, particularly for the case of the DUT and the SAM head phantom. To limit stair casing, the positioning of the DUT against the SAM phantom shall be achieved by performing transformations such as translations and rotations on the SAM phantom only. The body phantom should preferably be reconstructed using the built-in drawing features of the numerical simulation tool when available. It can be easily aligned with both the handset and the FDTD axes.

5.3 General mesh settings

For the FDTD method, the intrinsic problem of choosing a sufficiently small cell or grid size yet limit the memory requirements can be challenging. The wavelength in the material with the highest relative permittivity generally dictates the required minimum grid step. To mesh the free-space surrounding the phone and the phantom, a cell size corresponding to about $\lambda/30$ to $\lambda/10$ may be sufficient, where λ is the smallest wavelength corresponding to the wave propagation in the material with the highest relative permittivity. Since the relative permittivities of the materials present in a mobile phone are usually low – typically in the range 2 to 10 – the tissue equivalent liquid is expected to have the highest relative permittivity. Since this is generally insufficient for modelling the smaller components in a mobile phone, it may be necessary to further decrease the cell size to fully account for fine details such as slots or gaps or small components. The cell size may then be much smaller than the minimum cell size imposed by the highest relative permittivity of the materials present in the computational domain.

5.4 Simulation parameters

Practical considerations for the application of the FDTD such as voxel size, stability, absorbing boundaries are described in IEC/IEEE 62704-1:2017, Annex C.

5.5 DUT model

5.5.1 General

Prior to performing the SAR calculation using the head or the body phantom, the numerical simulation shall first be undertaken considering the DUT alone, i.e. free space configuration. The validity of the numerical model of the DUT shall be verified as described in Clause 7.

A DUT model normally contains many different solids, typically more than one hundred, making this model a very complex structure to handle. Given the complexity of recent generation wireless handsets used by consumers and the extensive time required for device modelling, the only practical approach for producing the FDTD mesh is by importing the mechanical CAD file of the DUT, and to automatically generate the FDTD model for the handset. The file with the model shall be exported from the mechanical engineering CAD tool in a format that can be easily imported into the FDTD simulation tool (usually SAT or IGES file format). Prior to the export of the CAD model, all parts shall be assembled and correctly aligned with respect to each other.

When the mechanical CAD file is not available, it may be acceptable to reconstruct the numerical model based on information such as the geometrical dimensions and positions of

the different components of the DUT [3]. In this document, the numerical model of the DUT is considered as a CAD model whether it is obtained following a numerical reconstruction or available as an export of a mechanical CAD file. The validity of the numerical model shall be demonstrated according to 7.4.

It is most important that the components present in the DUT model are assigned the correct material dielectric parameters. After import of the CAD file into the FDTD simulation tool, the correct material shall be assigned to each object to be meshed. The components and dielectric properties should be verified by a CAD engineer familiar with the physical and mechanical construction of the mobile phone.

Prior to meshing, the cell size requirements shall be established. This can be done in several ways, including automatic mesh generation, by a CAD object or group of objects, or manually. In order to provide an accurate mesh that will require minimal computer memory and run times, it is common practice to use a graded mesh, also called non-uniform mesh [4]. A graded mesh allows the FDTD mesh cell sizes to vary with position in one dimension. This approach allows smaller cells to be used where needed in order to accurately describe small but important CAD objects. A typical application for smaller mesh cells is in the antenna region which usually consists of slots.

While the above basic approach is a good start, there are exceptions that shall be considered. For example, the CAD objects may not have continuous surfaces. This can happen when the surface of the object is formed by the combination of separate facets and these facets may not join precisely at their intersections, leaving unintended gaps. This problem can be mitigated by "healing" the object manually to close the gaps (the healing feature is usually available in most commercially available FDTD simulation tools to fix connection problems among CAD objects to be fixed). However, for CAD objects with large gaps it may be impossible to develop an accurate FDTD mesh without manual intervention.

It is recommended that the larger metallic components or parts should be made into separate objects for which specific grid settings can be applied. In particular, the antenna model shall be a separate object so that this structure can be meshed as accurately as possible. The metallic parts of the model shall be aligned and connected so that artificial floating of electrically connected objects does not occur. Usually the printed circuit board (PCB) is not well represented in the CAD model. It is typically modelled as a few thin metallic layers interleaved with dielectric material [5]. However, it is acceptable to model the PCB as one thick solid metallic object. It is important to note that if the PCB is not correctly modelled, it will be seen as an invalid CAD model according to 7.4.

In order to optimize the computational resources, the components in the DUT model, for instance components located inside shielded cans, that are not expected to have noticeable impact to SAR distributions may be removed [6]. Consequently, such metallic components shall be given meshing priority over a component of lesser impact on SAR distribution. Components with the same material dielectric property that are in physical contact shall be united to form one solid. As a minimum requirement, essential parts such as antenna, chassis, PCB, display or screen, battery, other relatively large metallic components and the dielectric material supporting the antenna shall be modelled accurately. The meshing order of the objects or groups of objects shall be specified so that objects that touch, or perhaps even overlap, are correctly represented in the FDTD model.

Once the meshing has been completed, the resulting FDTD model of the handset shall be viewed and verified for accuracy. Critical areas such as the antenna region and other conductive components shall be carefully examined since the most important objects of the DUT model are the metallic components because they have the biggest impact on the SAR distribution.

As a guideline for the mesh generation, the components of the mobile phone that are expected to have the relatively highest impact on the SAR distribution are provided in 5.5.2 to 5.5.7.

5.5.2 Antenna

The antenna of the DUT is the most important component to be modelled and the grid step shall be chosen so as to resolve all details such as slots and gaps contained in it. Figure 1 shows the typical appearance of a top-mounted multi-band patch antenna for the GSM and UMTS frequency bands of operation.

iTeh STANDARD PREVIEW
(standards.iteh.ai) IEC

NOTE The two separate metallic elements constituting the antenna are highlighted.

Figure 1 – An example of a multi-band antenna consisting of two metallic elements for the GSM and UMTS frequency bands

The shape of this particular antenna is rather complex and the cell size shall be chosen such that all details are resolved. In particular, if the antenna consists of separate metallic elements, most often used for operations at higher and/or multiple frequency bands, it is important to use a cell size that is less than half the separation between the elements. In the example shown in Figure 1, a cell size of 0,25 mm or less is necessary along the z-axis because the gap between the left and the middle branches of the antenna is only 0,5 mm. In the actual meshing, at least three cells are required to model the separations; otherwise, the tangential field in the gap to the parasitic element will not be simulated correctly. Furthermore, to correctly model the slot on the right metallic element of this antenna, a similar cell size is required along the x-axis.

5.5.3 RF source

The antenna feed model shall be constructed according to the feed used in the actual device. Usually a coaxial feed is connected to a feeding pin, in which case a classic FDTD feed gap source model shall be used. The actual feeding pin shall be replaced with the FDTD source excitation gap, as shown in Figure 2, and there shall be a gap of at least one cell corresponding to the actual gap dimension in the DUT model.

When the antenna is fed by a different means (e.g. a microstrip line as shown in Figure 3), the excitation source shall be modelled accordingly so that it is representative of the feed.

Figure 2 – An example of a source gap position that is inserted in replacement of a real-life feeding spring pin

Figure 3 – An example of a microstrip feed line

5.5.4 PCB

The PCB is a sandwich structure that typically consists of several metallic sheets interleaved with dielectric layers. Modelling the PCB as a sandwiched structure has been found to be important in order to compute the losses in the PCB properly [5], but it requires a very fine cell size, usually 0,1 mm or less. Furthermore, it is usually difficult to model the interconnections between the different layers of the PCB. To alleviate this difficulty, the PCB should rather be modelled as a metallic solid since doing so is very unlikely to lead to under-estimation of the SAR.

5.5.5 Screen

The screen normally consists of several glass layers that may be merged into one solid object for simplicity, in which case an effective relative permittivity, typically an average of the different dielectric properties of the different materials, shall be used. If the screen contains metallic parts or conductive components, those parts shall be modelled as separate objects embedded in the display. For example, a metallic frame is sometimes placed around the screen.

The screen display is attached to the PCB at several points and there is sometimes a narrow gap between them. The cell size shall be small enough to resolve this gap properly and it can be necessary to increase the resolution around the screen to resolve the air gaps around it. This is important since high surface currents will flow on the metallic parts. If the screen is not correctly and properly connected to the PCB, a completely different SAR distribution may result.
