About the IEC

The International Electrotechnical Commission (IEC) is the leading global organization that prepares and publishes International Standards for all electrical, electronic and related technologies.

About IEC publications

The technical content of IEC publications is kept under constant review by the IEC. Please make sure that you have the latest edition, a corrigenda or an amendment might have been published.

IEC Catalogue - webstore.iec.ch/catalogue

The stand-alone application for consulting the entire bibliographical information on IEC International Standards, Technical Specifications, Technical Reports and other documents. Available for PC, Mac OS, Android Tablets and iPad.

IEC publications search - www.iec.ch/searchpub

The advanced search enables to find IEC publications by a variety of criteria (reference number, text, technical committee,...). It also gives information on projects, replaced and withdrawn publications.

IEC Just Published - webstore.iec.ch/justpublished

Stay up to date on all new IEC publications. Just Published details all new publications released. Available online and also once a month by email.

Electropedia - www.electropedia.org

The world's leading online dictionary of electronic and electrical terms containing more than 30 000 terms and definitions in English and French, with equivalent terms in 15 additional languages. Also known as the International Electrotechnical Vocabulary (IEV) online.

IEC Glossary - std.iec.ch/glossary

More than 60 000 electrotechnical terminology entries in English and French extracted from the Terms and Definitions clause of IEC publications issued since 2002. Some entries have been collected from earlier publications of IEC TC 37, 77, 86 and CISPR.

IEC Customer Service Centre - webstore.iec.ch/csc

If you wish to give us your feedback on this publication or need further assistance, please contact the Customer Service Centre: csc@iec.ch.

A propos de l'IEC

La Commission Electrotechnique Internationale (IEC) est la première organisation mondiale qui élabore et publie des Normes internationales pour tout ce qui a trait à l'électricité, à l'électronique et aux technologies apparentées.

A propos des publications IEC

Le contenu technique des publications IEC est constamment revu. Veuillez vous assurer que vous possédez l'édition la plus récente, un corrigendum ou amendement peut avoir été publié.

Catalogue IEC - webstore.iec.ch/catalogue

Application autonome pour consulter tous les renseignements bibliographiques sur les Normes internationales, Spécifications techniques, Rapports techniques et autres documents de l'IEC. Disponible pour PC, Mac OS, tablettes Android et iPad.

Recherche de publications IEC - www.iec.ch/searchpub

La recherche avancée permet de trouver des publications IEC en utilisant différents critères (numéro de référence, texte, comité d'études,...). Elle donne aussi des informations sur les projets et les publications remplacées ou retirées.

IEC Just Published - webstore.iec.ch/justpublished

Restez informé sur les nouvelles publications IEC. Just Published détaille les nouvelles publications parues. Disponible en ligne et aussi une fois par mois par email.

Electropedia - www.electropedia.org

Le premier dictionnaire en ligne de termes électroniques et électriques. Il contient plus de 30 000 termes et définitions en anglais et en français, ainsi que les termes équivalents dans 15 langues additionnelles. Egalement appelé Vocabulaire Electrotechnique International (IEV) en ligne.

Glossaire IEC - std.iec.ch/glossary

Plus de 60 000 entrées terminologiques électrotechniques, en anglais et en français, extraites des articles Termes et Définitions des publications IEC parues depuis 2002. Plus certaines entrées antérieures extraites des publications des CE 37, 77, 86 et CISPR de l'IEC.

INTERNATIONAL ELECTROTECHNICAL COMMISSION

ROTATING ELECTRICAL MACHINES –

Part 27-3: Dielectric dissipation factor measurement on stator winding insulation of rotating electrical machines

FOREWORD

- 1) The International Electrotechnical Commission (IEC) is a worldwide organization for standardization comprising all national electrotechnical committees (IEC National Committees). The object of IEC is to promote international co-operation on all questions concerning standardization in the electrical and electronic fields. To this end and in addition to other activities, IEC publishes International Standards, Technical Specifications, Technical Reports, Publicly Available Specifications (PAS) and Guides (hereafter referred to as “IEC Publication(s)”). Their preparation is entrusted to technical committees; any IEC National Committee interested in the subject dealt with may participate in this preparatory work. International, governmental and non-governmental organizations liaising with the IEC also participate in this preparation. IEC collaborates closely with the International Organization for Standardization (ISO) in accordance with conditions determined by agreement between the two organizations.
- 2) The formal decisions or agreements of IEC on technical matters express, as nearly as possible, an international consensus of opinion on the relevant subjects since each technical committee has representation from all interested IEC National Committees.
- 3) IEC Publications have the form of recommendations for international use and are accepted by IEC National Committees in that sense. While all reasonable efforts are made to ensure that the technical content of IEC Publications is accurate, IEC cannot be held responsible for the way in which they are used or for any misinterpretation by any end user.
- 4) In order to promote international uniformity, IEC National Committees undertake to apply IEC Publications transparently to the maximum extent possible in their national and regional publications. Any divergence between any IEC Publication and the corresponding national or regional publication shall be clearly indicated in the latter.
<https://standards.iteh.ai/catalog/standards/sist/88283cff-2761-465a-a951-54bec9ce0916/iec-60034-27-3-2015>
- 5) IEC itself does not provide any attestation of conformity. Independent certification bodies provide conformity assessment services and, in some areas, access to IEC marks of conformity. IEC is not responsible for any services carried out by independent certification bodies.
- 6) All users should ensure that they have the latest edition of this publication.
- 7) No liability shall attach to IEC or its directors, employees, servants or agents including individual experts and members of its technical committees and IEC National Committees for any personal injury, property damage or other damage of any nature whatsoever, whether direct or indirect, or for costs (including legal fees) and expenses arising out of the publication, use of, or reliance upon, this IEC Publication or any other IEC Publications.
- 8) Attention is drawn to the Normative references cited in this publication. Use of the referenced publications is indispensable for the correct application of this publication.
- 9) Attention is drawn to the possibility that some of the elements of this IEC Publication may be the subject of patent rights. IEC shall not be held responsible for identifying any or all such patent rights.

International Standard IEC 60034-27-3 has been prepared by IEC technical committee 2: Rotating machinery.

This first edition cancels and replaces the first edition of IEC TR 60894 published in 1987. This edition constitutes a technical revision.

This edition includes the following significant technical changes with respect to the previous edition:

- a) digital measurement of dissipation factor and capacitance included;
- b) limits for dissipation factor values given;
- c) detailed description of measuring techniques;
- d) extension of scope to complete windings.

The text of this standard is based on the following documents:

FDIS	Report on voting
2/1803/FDIS	2/1804/RVD

Full information on the voting for the approval of this standard can be found in the report on voting indicated in the above table.

This publication has been drafted in accordance with the ISO/IEC Directives, Part 2.

A list of all parts in the IEC 60034 series, published under the general title *Rotating electrical machines*, can be found on the IEC website.

The committee has decided that the contents of this publication will remain unchanged until the stability date indicated on the IEC web site under "<http://webstore.iec.ch>" in the data related to the specific publication. At this date, the publication will be

- reconfirmed,
- withdrawn,
- replaced by a revised edition, or
- amended.

INTRODUCTION

This International Standard provides guidelines for dielectric dissipation factor measurements on form-wound stator bars or coils as well as for complete windings.

The dielectric dissipation factor is a measure of the dielectric losses in the stator winding insulation. Measurement of dielectric dissipation factor is an appropriate means of assessing the quality of new and also aged stator winding insulation of rotating electrical machines. Especially, the method is useful for assessing the uniform quality of manufacturing and the dielectric behaviour of the insulation as a whole. For aged stator windings, the dielectric dissipation factor provides information about insulation condition.

The dielectric dissipation factor measurements give no indication of the distribution of loss within the insulation and – in contrast to off-line partial discharge measurements – do not permit localization of weak points of the insulation system.

The main principle is to measure the dielectric dissipation factor over a range of voltages and to derive different characteristic dielectric loss parameters as basis for the evaluation.

Empirical limits verified in practice can be used as a basis for evaluating the quality of stator winding insulation systems in manufacturing. Furthermore, trend evaluation, e.g. diagnostic tests as part of the functional evaluation of insulation systems or in connection with servicing and overhaul of rotating machines, can also provide information on ageing processes, necessary further measures and intervals between overhauls. However, such trend evaluations cannot be used to predict the time to failure of a stator winding insulation.

ROTATING ELECTRICAL MACHINES –

Part 27-3: Dielectric dissipation factor measurement on stator winding insulation of rotating electrical machines

1 Scope

This part of IEC 60034 provides guidelines for the test procedures and the interpretation of test results for dielectric dissipation factor measurements on the stator winding insulation of rotating electrical machines. These guidelines are valid for rotating electrical machines with conductive slot coatings operating at a rated voltage of 6 kV and higher.

This standard applies to individual form-wound stator bars and coils outside a core (uninstalled), individual stator bars and coils installed in a core and complete form-wound stator winding of machines in new or aged condition.

This International Standard applies to all kind of vacuum impregnated or resin-rich (fully-loaded) taped bars, coils and complete windings. It is not applicable to non-impregnated individual bars and coils or non-impregnated complete windings.

Requirements for the dielectric dissipation factor characteristics of individual form-wound stator bars and coils of machines with rating voltages from 6-kV and higher when tested with 50 Hz or 60 Hz alternating voltages are given.

IEC 60060-2, *High-voltage test techniques – Part 2: Measuring systems*

3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

3.1

rated voltage

U_N

voltage or voltage range between lines at the terminals (also called line-to-line voltage) assigned, generally by a manufacturer, for a specified operating condition of a machine

3.2

dielectric dissipation factor

$\tan \delta$

tangent of the dielectric loss angle δ (complement of the insulation power factor angle) at pre-determined values of temperature, frequency, and voltage or dielectric stress

Note 1 to entry: Other terms sometimes used for this property are tan delta, loss tangent, dielectric loss factor or dielectric power factor. Between the dielectric dissipation factor and the power factor (the cosine of power factor

angle or the sine of the dielectric loss angle) a physical difference exists, but the two measurements are very nearly the same, when the dielectric dissipation factor is lower than 100×10^{-3} (see 4.1).

Note 2 to entry: Although the dielectric dissipation factor $\tan \delta$ is expressed in absolute value in this standard, it is also expressed in percentage in other documents.

**3.3
delta tan delta**

$\Delta \tan \delta$

the difference in dielectric dissipation factor measured at two successive test voltages in steps of $0,2 U_N$ intervals

**3.4
tan delta tip-up**

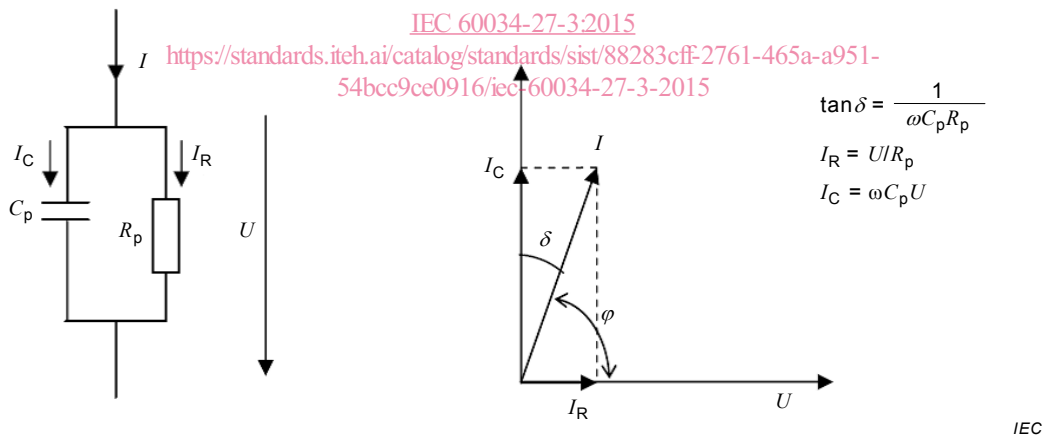

the difference in dielectric dissipation factor measured at the two voltages $0,6 U_N$ and $0,2 U_N$

Note 1 to entry: Dielectric dissipation factor differences with other voltage steps than mentioned in 3.3 and 3.4 may be used but the limits suggested in Table 1 will not be valid in that case.

4 Theory and measuring techniques

4.1 Dielectric dissipation factor measurement

As defined in 3.2, the dielectric dissipation factor $\tan \delta$ is the tangent of the dielectric loss angle δ (complement of the insulation power factor angle φ) at a predetermined voltage U , frequency and temperature. The dielectric loss of the insulation system can be represented by either a parallel (C_p, R_p) or a series (R_s, C_s) equivalent circuit diagram of elements respectively (see Figure 1 and Figure 2).

Key

- C_p parallel capacitance
- R_p parallel resistor
- ω $2\pi f$ angular frequency
- I_C current in capacitive path
- I_R current in resistive path
- U voltage at insulation system
- I total current through insulation system

IEC

Key

- C_s series capacitance
- R_s series resistor
- U voltage at insulation system
- I total current through insulation system
- U_C voltage at capacitance
- U_R voltage at resistor

Figure 2 – Series circuit and vector diagram

Comparison of the dielectric dissipation factor $\tan \delta$ and the sometimes otherwise used insulation power factor $\cos \varphi$ show that these values are very nearly the same, if the dielectric dissipation factor $\tan \delta$ is less than 100×10^{-3} , which may be presumed for all modern stator winding insulation systems.

NOTE The preferred and exclusive used loss characteristic in this standard is the dielectric dissipation factor $\tan \delta$. But in order to make possible a comparison between insulation power factor $\cos \varphi$ and dielectric dissipation factor $\tan \delta$ values, a table is given in Annex A.

As shown in Figure 1, the vector of insulation current I can be divided in two perpendicular components, which represent a capacitive current I_C (90° leading to voltage U) and a resistive current I_R (in phase with voltage U). The phase shift angle δ is caused by a resistive component in addition to the capacitive component of the insulation. The dielectric dissipation factor $\tan \delta$ can be expressed in the following equation:

$$\tan \delta = \omega C_s R_s = \frac{1}{\omega C_p R_p}$$

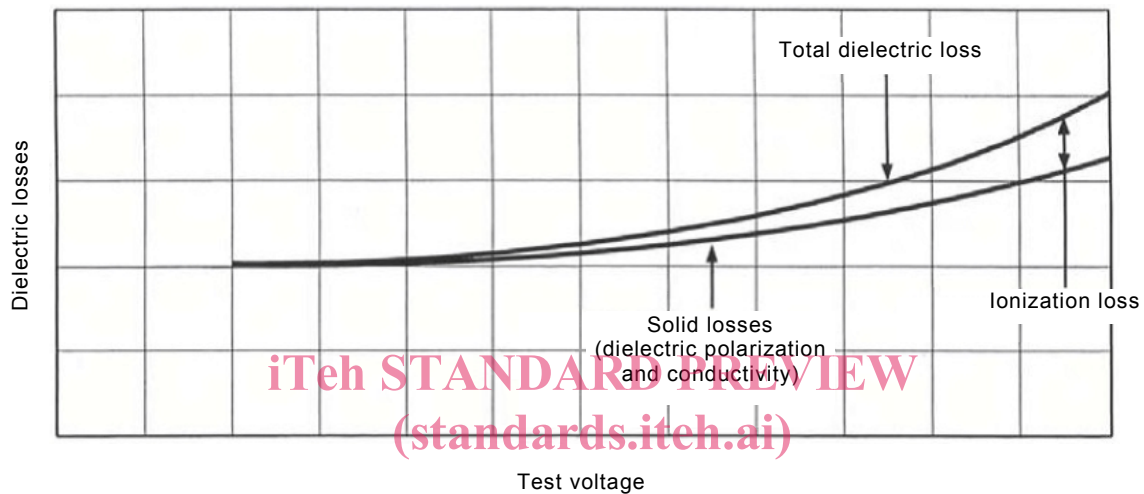

The capacitive component C_s or C_p represents the lossless capacitance of the tested insulation while the resistive component R_s or R_p summarizes the different kind of losses. The loss characteristics under consideration are those mainly relating to the main ground-wall insulation between the conductor structure (including inner conductor shield, if such exists), the conductive slot coating and the earthed enclosure. In the case of measurements on single stator bars or coils, only that part of the insulation which is dielectrically in series with the ground-wall insulation enters into the measurement result because guard ring electrodes can be used. In the case of dissipation factor measurements on complete windings, the action of the stress control coating and ambient surface condition have to be considered. These influencing factors may be important when comparing test results from different measurements.

Dielectric dissipation factor measurement at voltages below the inception of partial discharges represents the magnitude of dielectric losses in the solid insulation (dielectric absorption and conductive losses) and the conditions of electrical contact to the earthed measuring electrode. The dielectric dissipation factor component arising from the dielectric losses generally chang-

es very little with voltage, but a significantly higher than normal loss measured indicates some difference in the structure of the insulation, such as may arise from incorrect resin composition or inadequate cure.

When the test voltage is raised two different types of dielectric losses increase (see Figure 3):

- dielectric losses of the solid insulation material (polarization, conductivity);
- partial discharges within gaseous inclusions (voids) in the insulation structure cause an increase in dielectric dissipation factor and increasingly larger number of voids begin to undergo discharge with rising applied voltage. The value of dielectric loss and therefore the value of $\tan \delta$ will continue to increase.

Test voltage

Figure 3 – Dielectric losses with increasing voltage (schematic)

4.2 Analogue Schering bridge

Measurement is carried out by means of the analogue Schering bridge or an equivalent type of bridge like a transformer ratio arm bridge (see 4.3) or by means of modern digital measurement facilities (see 4.4). A variable amplitude alternating voltage supply is used, having sufficient rating to provide the measured voltage across the capacitance of the test object and complying with the requirements of IEC 60060-2. Figure 4 shows the basic circuit diagram for a high voltage Schering bridge, when measuring a stator winding bar or coil with an assumed lossless capacitance C_x and resistive losses of R_x , using a test circuit with guard ring electrodes. The high voltage branch of the bridge includes the high voltage standard capacitor (C_0) with very low dielectric losses. The Schering bridge instrument itself consists of the low voltage branches with variable sets of resistive (R_1 and R_2) and capacitive (C_1) decades of high precision. The balanced condition of the bridge, which is a necessary requirement for correct measurement, is monitored by a sensitive “Null indicator” (see Figure 4).

**Key**

Positions of earthing switch:	A for testing coils or bars not earthed

R_1 Variable resistance of balancing branch 1	R_x Resistance of test object

Figure 4 – High voltage Schering bridge – Basic circuit

<https://standards.iteh.ai/catalog/standards/sist/88283cff-2761-465a-a951-54bcc9ce0916/iec-60034-27-3-2015>

The analogue Schering bridge is very sensitive to disturbances produced by stray capacitance to earth potential. Therefore it is recommended to use double screened coaxial measuring cables with an active screen potential compensator, i.e. Wagner earth circuit.

Today, most analogue bridges like high voltage Schering bridge use an automated balancing procedure for that part of the bridge equipment which includes the low voltage branches with the variable bridge elements C_1 , R_1 and R_2 .

A high-voltage standard capacitor is used as a reference standard C_0 in the bridge circuit. The nominal value of the capacitance is typically 100 pF or 1 000 pF within a tolerance less than 5 % in long term behaviour. The dielectric dissipation factor of this standard capacitor should be less than $0,01 \times 10^{-3}$ up to the maximum test voltage.

4.3 Transformer ratio arm bridge

Another typical example of the analogue bridge is the transformer ratio arm bridge. The bridge is automated by applying a current comparator consisting of operational amplifiers and transformers. An example circuit is shown in Figure 5. Windings under the standard capacitor C_0 and the capacitance of test object C_x are wound in the reverse direction with each other around a magnetic core of high permeability. When the bridge is balanced by adjusting turn number N_s and adjustable resistor R_d , the flux or magnetomotive force in the magnetic core becomes zero. Then the potential of the points a and b is developed by the voltage drop across very small DC resistances of windings N_x and N_s and becomes virtually zero. This method eliminates influence of stray capacitances to the ground. Therefore this bridge method does not require the Wagner earth circuit which the Schering bridge requires.

Figure 5 – Transformer ratio arm bridge

4.4 Digital phase shift measurement

The development of digital electronics, particularly high resolution AD-converter and filter devices, resulted in digital dissipation factor and capacitance measuring systems which are completely computer controlled. One example of a test set-up with the high voltage circuit consisting of the test object (C_x , R_x) path and the reference path with standard capacitor C_0 and the electronic measuring equipment on the low voltage side is shown in Figure 6. The measuring principle is based on precise recording of the currents through the standard capacitor (reference) and the test object path with the high voltage as a reference marker. The dielectric dissipation factor is calculated from these currents, or by measurement of the phase difference between these currents. High sensitivity digital equipment for dissipation factor measurement can be characterised by the following parts:

- simultaneous measurement of sinusoidal wave current and voltage in both high voltage paths with high amplitude and time precision;
- suppression of harmonics and external noise at current and voltage sine-wave with digital filtering in time or frequency domain;
- sensitive and reliable measurement of current phase shift between reference path and test object path;
- calculation of dissipation factor $\tan \delta$ and capacitance C_x based on phase shift and amplitude information extracted from digital current measurement;

- display actual $\tan \delta$ and C_x values of stator winding insulation in correlation to the applied test voltage during computer controlled test procedure.

<https://standards.iteh.ai/catalog/standards/sist/88283cff-2761-465a-a951-54bcc9ce0916/iec-60034-27-3-2015>

IEC

Key

- C_0 capacitance of high precision standard capacitor without losses
 C_x, R_x insulation capacitance and resistance of bars or coils with dielectric losses

Figure 6 – Schematic test set-up of a digital dissipation factor measuring system with principle current oscillogram

If the measurement system uses high voltage insulated tools like e.g. fibre optic data links between measuring units and the control computer it can easily perform dissipation factor measurements on permanently earthed test objects like rotating machines in the field. Because the fibre optic cables act as a HV insulator, the battery powered measuring devices may be placed on high potential leads instead of low voltage connections to earth.

5 Test procedures

5.1 General

The dielectric dissipation factor test is applicable to stator winding components (bars or coils) in which the insulation is cured. This test is usable for single vacuum pressure impregnated or resin-rich (fully-loaded) bars, coils and complete windings including global vacuum pressure impregnation (VPI) technology. The test is not applicable to non-impregnated individual bars and coils or non-impregnated complete windings.

Dissipation factor measurement should be performed with AC line frequency voltage of sinusoidal wave shape and a low amount of harmonics according to IEC 60060-1.
