About the IEC

The International Electrotechnical Commission (IEC) is the leading global organization that prepares and publishes International Standards for all electrical, electronic and related technologies.

About IEC publications

The technical content of IEC publications is kept under constant review by the IEC. Please make sure that you have the latest edition, a corrigenda or an amendment might have been published.

IEC Catalogue - webstore.iec.ch/catalogue

The stand-alone application for consulting the entire bibliographical information on IEC International Standards, Technical Specifications, Technical Reports and other documents. Available for PC, Mac OS, Android Tablets and iPad.

Electropedia - www.electropedia.org

The world's leading online dictionary of electronic and electrical terms containing 21 000 terms and definitions in English and French, with equivalent terms in 16 additional languages. Also known as the International Electrotechnical Vocabulary (IEV) online.

IEC publications search - webstore.iec.ch/advsearchform

The advanced search enables to find IEC publications by a variety of criteria (reference number, text, technical committee,...). It also gives information on projects, replaced and withdrawn publications.

IEC Glossary - std.iec.ch/glossary

67 000 electrotechnical terminology entries in English and French extracted from the Terms and Definitions clause of IEC publications issued since 2002. Some entries have been collected from earlier publications of IEC TC 37, 77, 86 and CISPR.

IEC Just Published - webstore.iec.ch/justpublished

Stay up to date on all new IEC publications. Just Published details all new publications released. Available online and also once a month by email.

IEC Customer Service Centre - webstore.iec.ch/csc

If you wish to give us your feedback on this publication or need further assistance, please contact the Customer Service Centre: sales@iec.ch.

INTERNATIONAL ELECTROTECHNICAL COMMISSION

NANOTECHNOLOGY – RELIABILITY ASSESSMENT –

Part 2-1: Nano-enabled photovoltaic devices – Stability test

FOREWORD

- 1) The International Electrotechnical Commission (IEC) is a worldwide organization for standardization comprising all national electrotechnical committees (IEC National Committees). The object of IEC is to promote international co-operation on all questions concerning standardization in the electrical and electronic fields. To this end and in addition to other activities, IEC publishes International Standards, Technical Specifications, Technical Reports, Publicly Available Specifications (PAS) and Guides (hereafter referred to as “IEC Publication(s)”). Their preparation is entrusted to technical committees; any IEC National Committee interested in the subject dealt with may participate in this preparatory work. International, governmental and non-governmental organizations liaising with the IEC also participate in this preparation. IEC collaborates closely with the International Organization for Standardization (ISO) in accordance with conditions determined by agreement between the two organizations.
- 2) The formal decisions or agreements of IEC on technical matters express, as nearly as possible, an international consensus of opinion on the relevant subjects since each technical committee has representation from all interested IEC National Committees.
- 3) IEC Publications have the form of recommendations for international use and are accepted by IEC National Committees in that sense. While all reasonable efforts are made to ensure that the technical content of IEC Publications is accurate, IEC cannot be held responsible for the way in which they are used or for any misinterpretation by any end user.
- 4) In order to promote international uniformity, IEC National Committees undertake to apply IEC Publications transparently to the maximum extent possible in their national and regional publications. Any divergence between any IEC Publication and the corresponding national or regional publication shall be clearly indicated in the latter.
- 5) IEC itself does not provide any attestation of conformity. Independent certification bodies provide conformity assessment services and, in some areas, access to IEC marks of conformity. IEC is not responsible for any services carried out by independent certification bodies.
- 6) All users should ensure that they have the latest edition of this publication.
- 7) No liability shall attach to IEC or its directors, employees, servants or agents including individual experts and members of its technical committees and IEC National Committees for any personal injury, property damage or other damage of any nature whatsoever, whether direct or indirect, or for costs (including legal fees) and expenses arising out of the publication, use of, or reliance upon, this IEC Publication or any other IEC Publications.
- 8) Attention is drawn to the Normative references cited in this publication. Use of the referenced publications is indispensable for the correct application of this publication.
- 9) Attention is drawn to the possibility that some of the elements of this IEC Publication may be the subject of patent rights. IEC shall not be held responsible for identifying any or all such patent rights.

The main task of IEC technical committees is to prepare International Standards. In exceptional circumstances, a technical committee may propose the publication of a Technical Specification when

- the required support cannot be obtained for the publication of an International Standard, despite repeated efforts, or
- the subject is still under technical development or where, for any other reason, there is the future but no immediate possibility of an agreement on an International Standard.

Technical Specifications are subject to review within three years of publication to decide whether they can be transformed into International Standards.

IEC 62876-2-1, which is a Technical Specification, has been prepared by IEC technical committee 113: Nanotechnology for electrotechnical products and systems.

The text of this Technical Specification is based on the following documents:

Enquiry draft	Report on voting
113/334/DTS	113/421/RVDTS

Full information on the voting for the approval of this Technical Specification can be found in the report on voting indicated in the above table.

This document has been drafted in accordance with the ISO/IEC Directives, Part 2.

The committee has decided that the contents of this document will remain unchanged until the stability date indicated on the IEC website under "<http://webstore.iec.ch>" in the data related to the specific document. At this date, the document will be

- transformed into an International Standard,
- reconfirmed,
- withdrawn,
- replaced by a revised edition, or
- amended.

A bilingual version of this publication may be issued at a later date.

INTRODUCTION

Nano-enabled photovoltaics (NePV) is a novel format of photovoltaic technology that can be manufactured in large-area, flexible, thin sheets through solution processing or vapour deposition. Many of the materials involved are nanomaterials and organic semiconductors. They improve the conversion of sunlight into free electrons and support the extraction of the electrons out of the device. Furthermore, nanomaterials are used as boundary layers and act as protective coatings to increase the stability of the PV device. NePV has the potential to provide low-cost renewable energy due to relatively inexpensive, high-throughput manufacturing and low material costs, as a result of the use of low-cost flexible polymeric substrates and packaging films [1]. In addition, NePV is expected to enable new products due to its light weight, flexibility, ability to adapt and tune colour appearance and good efficiency at low light levels, which is conducive to indoor use. Due to these properties NePV is attracting more attention from a variety of groups with a view to improving the efficiency and stability, which has resulted in significant efficiency gains through achievements in materials engineering and process optimization. Concerning stability, however, improvements have not been evident and have not been demonstrated, since standardized testing methods do not exist. In order to commercialize NePV, its stability must be addressed and means for properly comparing stability need to be developed.

Within the scope of this document, NePV refers to photovoltaic devices made from nano-sized material entities, involving a combination of organic and inorganic components and hard and soft matter, sometimes including liquid electrolytes, which are combined using low-cost preparation methods mainly by low-temperature solution processing. The developments of these types of solar cells are primarily through four main directions: organic polymers or small molecules (OPV), dye sensitized solar cells (DSSC), organic/inorganic hybrid solar cells and quantum dot based solar cells. The procedures outlined in this document were designed for NePV, but may be extended to serve as a guideline for early stability assessment for new materials or processes for other photovoltaic technologies as well.

Stability assessment standards define the conditions for a set of stress tests, which address isolated stress factors that can lead to failure in a service environment, in order to allow developers to test under repeatable conditions and to quantitatively compare the stability of photovoltaic devices subjected to these conditions. Several such stability assessment protocols have been proposed by the International Summit on OPV Stability (ISOS) of the OPV community [2,3]. The test conditions defined in this document are based on the ISOS protocol by selecting and modifying the conditions so that they are applicable to a range of NePV devices. True reliability prediction and quantification, however, requires significantly more extensive testing and is not within the scope of this document.

The objectives of this document are to specify the requirements for a general stability assessment standard (SAS) for NePV intended to be used in but not limited to outdoor environments; give direction to developers and engineers developing NePV devices, to guide test laboratories on testing, and to allow for a quantitative stability comparison between different technologies. It is not intended that the requirements specified in this document are to be used for device-type approval or certification. This document simply provides a set of tests for stability assessment and establishes the minimum reporting requirements in order to guide the community through a process of technology improvement by achieving comparable measurements and allowing improvement in device stability to be measured in a qualified and comparable methodology. More specific test conditions for specific devices and/or for specific applications should be developed separately in the future.

The general procedure for the recommended stability testing procedure is to measure device performances before and at certain intervals after applying well defined stresses to NePV devices, in order to track the performance changes due to the applied stresses. Not all recommended tests or stress conditions need to be performed at all stages of development. In the early stages of development a subset of tests which are relatively easy to implement, e.g. dry-heat, damp-heat and light exposure, should be performed first to achieve a first information about the general stability of the tested system. As development of a particular technology progresses and the technology matures, it is recommended to add more

sophisticated tests as deemed necessary. Retesting at later stages for regular process control and materials monitoring should also be considered to identify problems. The tests single out certain stress factors that are expected to frequently occur during outdoor exposure. In this document each of the tests is intended to be performed on a new set of devices in order to determine the most detrimental stress factors and aid in an optional failure mode analysis. Sequential tests in various conditions may be performed, but the results are expected to be difficult to interpret. To include the effect of multiple and varied stresses, a laboratory weathering test was adapted and included.

NePV will incorporate many polymeric materials such as binders for nano-materials, substrates, adhesives and packaging materials, which may have a strong interaction with the NePV photovoltaic active layers of the devices under test, and may therefore affect the stability of the device as a whole. To address this, the stability tests in this document are closely related to those used in artificial weathering for polymers. The stability tests outlined in this document could be a component of an exhaustive failure analysis in order to identify the causes of performance losses, which can be the result of many different issues. The procedures described in this document are focused but not limited to nano-enabled PV devices. The document outlines minimal equipment and procedural practices. Stability should always be regarded as a system property. As layers or materials in the system are changed (including in the packaging), retesting will be necessary to ensure that stability is not affected in a detrimental manner.

This document makes no specific recommendation about the materials and device structures to be tested, and can be applied to a wide variety of systems. A generic picture of a device under test is shown in Figure 1.

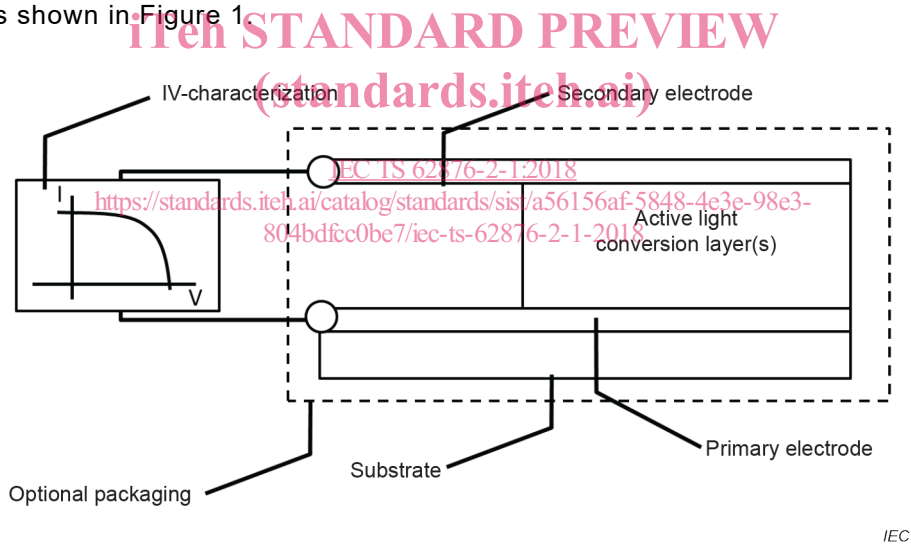

Figure 1 – Generic representation of a device under test during IV-characterization

This document is meant to be a general document that can be applied to all NePV devices. As such, it is not intended to be used as a standard for assembled photovoltaic modules. The stress tests are specific and explicitly defined to establish consistency of test procedures and reporting of reliability information.

NANOTECHNOLOGY – RELIABILITY ASSESSMENT –

Part 2-1: Nano-enabled photovoltaic devices – Stability test

1 Scope

This part of IEC 62876, which is a Technical Specification, establishes a general stability testing programme to verify the stability of the performance of nanomaterials and nano-enabled photovoltaic devices (NePV) devices. These devices are used as subassemblies for the fabrication of photovoltaic modules through a combination with other components. This testing programme defines standardized degradation conditions, methodologies and data assessment for technologies. The results of these tests define a stability under standardized degradation conditions for quantitative evaluation of the stability of a new technology. The procedures outlined in this document were designed for NePV, but can be extended to serve as a guideline for other photovoltaic technologies as well.

NOTE 1 The tests in this document are selected with outdoor use in mind, and as such represent isolated stress factors that devices will be exposed to in outdoor environments. For indoor environments, the stresses faced by the devices in operation are significantly less severe, and not all tests will be applicable. Despite this, the suggested tests provide a means of tracking stability improvements and can provide valuable data during device development.

NOTE 2 The performance of devices will be evaluated before and after the application of the stress tests. The efficiency characterization methods for NePV have not been fully established at present. In the text, notes are therefore added regarding the efficiency characterization. The notes particularly address issues to be discussed in the future for applications such as indoor use, or devices with a slow response or uncommon spectral responses such as tandem cells.

NOTE 3 The scope does not include photovoltaic modules, i.e. the final product. It is only intended to test the technology.

3 Terms, definitions and abbreviated terms

NOTE A comprehensive nanotechnology vocabulary is under joint development in IEC TC 113 and ISO/TC 229. The vocabulary is being published as different parts of the 80004 Technical Specification. This document is harmonized with the terms and definitions of the 80004 Technical Specification at the time of publication and will be kept harmonized during the maintenance of the document. Definitions not yet specified are taken from scientific literature.

3.1 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

- IEC Electropedia: available at <http://www.electropedia.org/>
- ISO Online browsing platform: available at <http://www.iso.org/obp>

3.1.1

nano enabled photovoltaic device NePV

photovoltaic device in which the conversion of light into electrical energy is enabled or significantly enhanced by nanotechnology

Note 1 to entry Nano-enabled photovoltaics refers to photovoltaic devices and semi-finished products in which one or more of the active light conversion materials are based on a nano-material or semiconductor. NePV includes bulk-heterojunction photovoltaic devices made from organic polymers or small molecules, as well as dye-sensitized solar cells and hybrid solar cells made from both organic and inorganic materials. NePV includes photovoltaic devices made from inorganic nanoparticles as well.

3.1.2

device under test

DUT

representative device used in testing

Note 1 to entry Nano-enabled photovoltaic devices consist of multiple functional layers which are mechanically and electrically connected or are applied (e.g by printing) on a flexible or rigid substrate. For test purposes, samples are recommended to have dimensions that are representative of the technology and allow for a conclusion that a technology can be produced on a larger scale. For this purpose, a suitable minimum aperture area of the NePV devices used in the stability assessment is large enough to test area effects and minimize edge effects (a recommended device area is approx. 1 cm² or larger in accordance with the standards for efficiency certification of PV-devices). This document is intended to guide and facilitate the development of new technologies, and NePV devices subjected to these tests are intended to be unpackaged or packaged semi-finished devices that are not finished products for the end user.

3.1.3

IV-characterization

measurement of the current-voltage characteristic

Note 1 to entry:

- a) Artificial irradiation light sources other than terrestrial solar light are generally used for characterization.
- b) For irradiation light sources other than specified in IEC 60904, the total light intensity can be properly determined from the absolute device spectral response and irradiation light spectrum. It is recommended that the irradiation light spectrum and absolute device spectral response is documented in the test report. [1]
- c) Due to the nature of NePV as defined in 3.1.1, specifically designed algorithms for IV-characterization may be applied, e.g. [2]. It is recommended that the algorithms are documented in detail in the test report.
