This European Standard was approved by CEN on 15 March 2005.

CEN members are bound to comply with the CEN/CENELEC Internal Regulations which stipulate the conditions for giving this European Standard the status of a national standard without any alteration. Up-to-date lists and bibliographical references concerning such national standards may be obtained on application to the Central Secretariat or to any CEN member.

This European Standard exists in three official versions (English, French, German). A version in any other language made by translation under the responsibility of a CEN member into its own language and notified to the Central Secretariat has the same status as the official versions.

CEN members are the national standards bodies of Austria, Belgium, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Slovakia, Slovenia, Spain, Sweden, Switzerland and United Kingdom.

SIST EN 1892:2005
<https://standards.itech.ai/catalog/standards/sist/1b06076f-a664-4775-8cf4-474c0dc7f8b2/sist-en-1892-2005>

Foreword

This document (EN 1892:2005) has been prepared by Technical Committee CEN/TC 184 "Advanced technical ceramics", the secretariat of which is held by BSI.

This European Standard shall be given the status of a national standard, either by publication of an identical text or by endorsement, at the latest by October 2005, and conflicting national standards shall be withdrawn at the latest by October 2005.

This document supersedes ENV 1892:1996.

According to the CEN/CENELEC Internal Regulations, the national standards organizations of the following countries are bound to implement this European Standard: Austria, Belgium, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Slovakia, Slovenia, Spain, Sweden, Switzerland and United Kingdom.

EN 1892:2005 (E)

1 Scope

This document specifies the conditions for determination of tensile properties of ceramic matrix composite materials with continuous fibre reinforcement for temperatures up to 2 000 °C under vacuum or a gas atmosphere which is inert to the material under test.

NOTE The use of these environments is aimed at avoiding changes of the material to be tested due to chemical reaction with its environment during the test.

This document applies to all ceramic matrix composites with a continuous fibre reinforcement, unidirectional (1D), bidirectional (2D), and tridirectional (x D, with $2 < x \leq 3$), loaded along one principal axis of reinforcement.

2 Normative references

The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

EN 10002-4; *Metallic materials - Tensile test - Part 4: Verification of extensometers used in uniaxial testing*

EN 60584-1, *Thermocouples; Part 1: Reference tables (IEC 60584-1:1995)*

EN 60584-2, *Thermocouples; Part 2: Tolerances (IEC 60584-2:1982 + A1:1989)*

EN ISO 7500-1, *Metallic materials — Verification of static uniaxial testing machines — Part 1: Tension/compression testing machines — Verification and calibration of the force-measuring system. (ISO 7500-1:2004)*

ISO 3611, *Micrometer callipers for external measurement*

3 Terms, definitions and symbols

For the purposes of this document, the following terms, definitions and symbols apply.

- 3.1**
test temperature, T
temperature of the test piece at the centre of the gauge length
- 3.2**
calibrated length, l
part of the test specimen which has uniform and minimum cross-section area
- 3.3**
gauge length, L_0
initial distance between reference points on the test specimen in the calibrated length
- 3.4**
controlled temperature zone
part of the calibrated length including the gauge length where the temperature is controlled to within 50 °C of the test temperature
- 3.5**
initial cross-section area, S_0
initial cross-section area of the test specimen within the calibrated length, at test temperature

3.6**longitudinal deformation, Δ**

increase in the gauge length between reference points under a tensile force.

3.7**longitudinal deformation under maximum tensile force, Δ_m**

increase in the gauge length between reference points under maximum tensile force

3.8**tensile strain, ϵ**

relative change in the gauge length defined as the ratio Δ/L_0

3.9**tensile strain under maximum tensile force, ϵ_m**

relative change in the gauge length defined as the ratio Δ/L_0 corresponding to the maximum force

3.10**tensile stress, σ**

tensile force supported by the test specimen at any time in the test divided by the initial cross-section area

3.11**maximum tensile force, F_m**

highest recorded tensile force in a tensile test on the test specimen when tested to failure

3.12**tensile strength, σ_m**

ratio of the maximum tensile force to the initial cross-section area

3.13**proportionality ratio or pseudo-elastic modulus EP**

slope of the linear section of the stress-strain curve, if any.

NOTE

Examination of the stress-strain curves for ceramic matrix composites allows definition of the following cases:

- a) material with a linear section in the stress-strain curve;

For ceramic matrix composites that have a mechanical behaviour characterised by a linear section, the proportionality ratio is defined as:

$$EP(\sigma_1, \sigma_2) = \frac{(\sigma_2 - \sigma_1)}{(\epsilon_2 - \epsilon_1)} \quad (1)$$

where

(ϵ_1, σ_1) and (ϵ_2, σ_2) lie near the lower and the upper limits of the linear section of the stress-strain curve.

The proportionality ratio or pseudo-elastic modulus is termed the elastic modulus, E , in the single case where the linearity starts near the origin.

- b) material with no-linear section in the stress-strain curve.

In this case only stress-strain couples can be fixed.

EN 1892:2005 (E)

4 Principle

A test specimen of specified dimensions is heated to the test temperature, and loaded in tension. The test is performed at constant crosshead displacement rate, or constant deformation rate (or constant loading rate). Force and longitudinal deformation are measured and recorded simultaneously.

NOTE 1 The test duration is limited to reduce creep effects.

NOTE 2 When constant loading rate is used in the non-linear region of the tensile curve, only the tensile strength can be obtained from the test. In this region constant crosshead displacement rate or constant deformation rate is recommended to obtain the complete curve.

5 Apparatus

5.1 Test machine

The test machine shall be equipped with a system for measuring the force applied to the test specimen conforming to grade 1 or better according to EN ISO 7500-1.

This shall apply during actual test conditions of, e.g. gas pressure and temperature.

5.2 Load train

The load train configuration shall ensure that the load indicated by the load cell and the load experienced by the test specimen are the same.

The load train performance, including the alignment system and the force transmitting system, shall not change because of heating.

The attachment fixtures shall align the test specimen axis with the applied force direction.

NOTE 1 The alignment should be verified and documented, according to, for example the procedure described in the HTMTC code of practice [1].

The grip design shall prevent the test specimen from slipping.

There are two types of gripping systems.

- hot grips where the grips are in the hot zone of the furnace;
- cooled grips where the grips are outside the hot zone.

NOTE 2 The choice of gripping system will depend on material, on test specimen design and on alignment requirements.

NOTE 3 The hot grip technique is limited in temperature because of the nature and strength of the materials that can be used for grips.

NOTE 4 In the cooled grip technique, a temperature gradient exists between the centre which is at the prescribed temperature and the ends which are at the same temperature as the grips.

5.3 Test chamber

The test chamber shall be gas tight and shall allow proper control of the test specimen environment in the vicinity of the test specimen during the test.

The installation shall be such that the variation of the load due to the variation of pressure is less than 1 % of the scale of the load cell being used.

Where a gas atmosphere is used, the gas atmosphere shall be chosen depending on the material to be tested and on test temperature. The level of pressure shall be chosen depending: on the material to be tested, on temperature, on the type of gas, and on the type of extensometry.

Where a vacuum chamber is used, the level of vacuum shall not induce chemical and/or physical instabilities of the test specimen material, and of extensometer rods, when applicable.

5.4 Set-up for heating

The set-up for heating shall be constructed in such a way that the temperature gradient within the gauge length is less than 20 °C at test temperature.

5.5 Extensometer

The extensometer shall be capable of continuously recording the longitudinal deformation at test temperature and conforming to class 1 or better, in accordance with EN 10002-4.

NOTE 1 The use of an extensometer with the greatest gauge length is recommended.

The linearity tolerances shall be lower than 0,05 % of the extensometer range used.

Two commonly used types of extensometer are the mechanical extensometer and the electro-optical extensometer.

Using a mechanical extensometer, the gauge length is the longitudinal distance between the two locations where the extensometer rods contact the test specimen.

The rods may be exposed to temperatures higher than the test specimen temperature. Temperature and/or environment induced structural changes in the rod material shall not affect the accuracy of deformation measurement. The material used for the rods shall be compatible with the test specimen material.

NOTE 2 Care should be taken to correct for changes in calibration of the extensometer that may occur as a result of operating under conditions different from calibration.

NOTE 3 Rod pressure onto the test specimen should be the minimum necessary to prevent slipping of the extensometer rods.

In the case of an electro-optical extensometer, electro-optical measurements in transmission require reference marks on the test specimen. For this purpose rods or flags shall be attached to the surface perpendicularly to its axis. The gauge length shall be the distance between the two reference marks. The material used for marks (and adhesive if used) shall be compatible with the test specimen material and the test temperature and shall not modify the stress field in the specimen.

NOTE 4 The use of integral flags as parts of the test specimen geometry is not recommended because of stress concentration induced by such features.

5.6 Temperature measurement devices

For temperature measurement, either thermocouples conforming to EN 60584-1 and EN 60584-2 shall be used, or, where thermocouples not conforming to EN 60584-1 and EN 60584-2 or pyrometers are used, calibration data shall be annexed to the test report.

EN 1892:2005 (E)

5.7 Data recording system

A calibrated recorder may be used to record force-deformation curve. The use of a digital data recording system combined with an analogue recorder is recommended.

5.8 Micrometers

Micrometers used for the measurement of the dimensions of the test specimen shall conform to ISO 3611.

6 Test specimens

6.1 General

The choice of specimen geometry depends on:

- nature of the material and of the reinforcement structure;
- type of heating system;
- type of gripping system.

The volume in the gauge length shall be representative of the material.

NOTE The total length L depends on furnace and gripping system. Generally, L is greater than 150 mm.

6.2 Test specimens commonly used with a hot gripping system

Several types of test specimens may be used, as indicated in Figures 1 to 3 and Tables 1 to 3.
