Foreword

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialized system for worldwide standardization. National bodies that are members of ISO or IEC participate in the development of International Standards through technical committees established by the respective organization to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organizations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work.

In the field of information technology, ISO and IEC have established a joint technical committee, ISO/IEC JTC 1. Draft International Standards adopted by the joint technical committee are circulated to national bodies for voting. Publication as an International Standard requires approval by at least 75% of the national bodies casting a vote.

International Standard ISO/IEC 10181-1 was prepared by Joint Technical Committee ISO/IEC JTC 1, Information technology, Subcommittee SC 21, Open systems interconnection, data management and open distributed processing, in collaboration with ITU-T. The identical text is published as ITU-T Recommen-465b-9ac4-dation X.810.

ISO/IEC 10181 consists of the following parts, under the general title *Information technology — Open Systems Interconnection — Security frameworks for open systems*:

- Part 1: Overview
- Part 2: Authentication framework
- Part 3: Access control framework
- Part 4: Non-repudiation framework
- Part 5: Confidentiality framework
- Part 6: Integrity framework
- Part 7: Security audit and alarms framework

Annexes A and B of this part of ISO/IEC 10181 are for information only.

Introduction

Many applications have requirements for security to protect against threats to the communication of information. Some commonly known threats, together with the security services and mechanisms that can be used to protect against them are described in CCITT Rec. X.800 | ISO 7498-2.

This Recommendation | International Standard defines the framework within which security services for open systems are specified.

ISO/IEC 10181-1: 1996 (E)

INTERNATIONAL STANDARD

ITU-T RECOMMENDATION

INFORMATION TECHNOLOGY – OPEN SYSTEMS INTERCONNECTION – SECURITY FRAMEWORKS FOR OPEN SYSTEMS: OVERVIEW

1 Scope

The security frameworks address the application of security services in an Open Systems environment, where the term *Open Systems* is taken to include areas such as Database, Distributed Applications, ODP and OSI. The security frameworks are concerned with defining the means of providing protection for systems and objects within systems, and with the interactions between systems. The security frameworks are not concerned with the methodology for constructing systems or mechanisms.

The security frameworks address both data elements and sequences of operations (but not protocol elements) which are used to obtain specific security services. These security services may apply to the communicating entities of systems as well as to data exchanged between systems, and to data managed by systems.

The security frameworks provide the basis for further standardization, providing consistent terminology and definitions of generic abstract service interfaces for specific security requirements. They also categorize the mechanisms that can be used to achieve those requirements.

One security service frequently depends on other security services, making it difficult to isolate one part of security from the others. The security frameworks address particular security services, describe the range of mechanisms that can be used to provide the security services, and identify interdependancies between the services and the mechanisms. The description of these mechanisms may involve a reliance on a different security service, and it is in this way that the security frameworks describe the reliance of one security service on another.

This part of the security frameworks:

2a6cb35ad728/iso-iec-10181-1-1996

- describes the organization of the security frameworks;
- defines security concepts which are required in more than one part of the security frameworks;
- describes the inter-relationship of the services and mechanisms identified in other parts of the frameworks.

2 Normative references

The following Recommendations and International Standards contain provisions, which through reference in this text, constitute provisions of this Recommendation | International Standard. At the time of publication, the editions indicated were valid. All Recommendations and Standards are subject to revision, and parties to agreements based on this Recommendation | International Standard are encouraged to investigate the possibility of applying the most recent edition of the Recommendations and Standards indicated below. Members of IEC and ISO maintain registers of currently valid International Standards. The Telecommunication Standardization Bureau of the ITU maintains a list of currently valid ITU Recommendations.

2.1 Identical Recommendations | International Standards

- ITU-T Recommendation X.200 (1994) | ISO/IEC 7498-1:1994, Information technology - Open Systems Interconnection - Basic Reference Model: The Basic Model.

2.2 Paired Recommendations | International Standards equivalent in technical content

 CCITT Recommendation X.800 (1991), Security architecture for Open Systems Interconnection for CCITT applications.

ISO 7498-2:1989, Information processing systems – Open Systems Interconnection – Basic Reference Model – Part 2: Security Architecture.

3 **Definitions**

The following definitions are used either in the overview or are common to two or more of the subsequent parts of the security frameworks.

For the purposes of this Recommendation | International Standard, the following definitions apply.

Basic Reference Model definitions 3.1

This Recommendation | International Standard makes use of the following terms defined in ITU-T Rec. X.200 | ISO/IEC 7498-1:

- (N)-layer;
- (N)-entity;
- (N)-protocol-data-unit;
- application process;
- real open system;
- real system.

3.2 Security architecture definitions

This Recommendation | International Standard makes use of the following terms defined in CCITT Rec. X.800 | ISO 7498-2:

- access control;
- availability;
- ciphertext; cryptographic checkvalue;
- (standards.iteh.ai) decipherment;
- denial of service;
 - ISO/IEC 10181-1:1996
- digital signature; https://standards.iteh.ai/catalog/standards/sist/a448830c-59ac-465b-9ac4encipherment; 2a6cb35ad728/iso-iec-10181-1-1996
- insider threat;
- key;
- key management;
- plaintext;
- outsider threat;
- security audit;
- security label;
- security policy;
- sensitivity;
- threat.

3.3 **Additional definitions**

For the purposes of this Recommendation | International Standard, the following definitions apply:

asymmetric cryptographic algorithm: An algorithm for performing encipherment or the corresponding decipherment in which the keys used for encipherment and decipherment differ.

NOTE - With some asymmetric cryptographic algorithms, decipherment of ciphertext or the generation of a digital signature requires the use of more than one private key.

- certification authority: An entity that is trusted (in the context of a security policy) to create security certificates containing one or more classes of security-relevant data.
- 3.3.3 conditionally trusted entity: An entity that is trusted in the context of a security policy, but which cannot violate the security policy without being detected.

- **3.3.4 cryptographic chaining**: A mode of use of a cryptographic algorithm in which the transformation performed by the algorithm depends on the values of previous inputs or outputs.
- 3.3.5 digital fingerprint: A characteristic of a data item, such as a cryptographic checkvalue or the result of performing a one-way hash function on the data, that is sufficiently peculiar to the data item that it is computationally infeasible to find another data item that will possess the same characteristics.
- **3.3.6 distinguishing identifier**: Data that uniquely identifies an entity.
- **3.3.7** hash function: A (mathematical) function that maps values from a (possibly very) large set of values into a smaller range of values.
- 3.3.8 one-way function: A (mathematical) function that is easy to compute but, when knowing a result, it is computationally infeasible to find any of the values that may have been supplied to obtain it.
- 3.3.9 one-way hash function: A (mathematical) function that is both a one-way function and a hash function.
- **3.3.10 private key**: A key that is used with an asymmetric cryptographic algorithm and whose possession is restricted (usually to only one entity).
- **3.3.11 public key**: A key that is used with an asymmetric cryptographic algorithm and that can be made publicly available.
- **3.3.12** revocation certificate: A security certificate issued by a security authority to indicate that a particular security certificate has been revoked.
- **3.3.13** revocation list certificate: A security certificate that identifies a list of security certificates that have been revoked.
- 3.3.14 seal: A cryptographic checkvalue that supports integrity but does not protect against forgery by the recipient (i.e. it does not provide non-repudiation). When a seal is associated with a data element, that data element is said to be sealed.
- NOTE Although a seal does not by itself provide non-repudiation, some non-repudiation mechanisms make use of the integrity service provided by seals, e.g. to protect communications with trusted third parties.
- 3.3.15 secret key: A key that is used with a symmetric cryptographic algorithm. Possession of a secret key is restricted (usually to two entities).

 ISO/IEC 10181-1:1996

 https://standards.iteh.ai/catalog/standards/sist/a448830c-59ac-465b-9ac4-
- **3.3.16** security administrator: A person who is responsible for the definition or enforcement of one or more parts of a security policy.
- **3.3.17** security authority: An entity that is responsible for the definition, implementation or enforcement of security policy.
- **3.3.18** security certificate: A set of security-relevant data issued by a security authority or trusted third party, together with security information which is used to provide the integrity and data origin authentication services for the data.
- NOTE All certificates are deemed to be security certificates (see the relevant definitions in ISO 7498-2). The term security certificate is adopted in order to avoid terminology conflicts with ITU-T Rec. X.509 | ISO/IEC 9594-8 (i.e. the directory authentication standard).
- **3.3.19** security certificate chain: An ordered sequence of security certificates, in which the first security certificate contains security-relevant information, and each subsequent security certificate contains security information which can be used in the verification of previous security certificates.
- **3.3.20** security domain: A set of elements, a security policy, a security authority and a set of security-relevant activities in which the set of elements are subject to the security policy for the specified activities, and the security policy is administered by the security authority for the security domain.
- **3.3.21** security domain authority: A security authority that is responsible for the implementation of a security policy for a security domain.
- **3.3.22** security information: Information needed to implement security services.
- 3.3.23 security recovery: Actions that are taken and procedures that are carried out when a violation of security is either detected or suspected to have taken place.
- **3.3.24** secure interaction rules: Security policy rules that regulate interactions between security domains.
- **3.3.25** security policy rules: A representation of a security policy for a security domain within a real system.

- **3.3.26** security token: A set of data protected by one or more security services, together with security information used in the provision of those security services, that is transferred between communicating entities.
- **3.3.27 symmetric cryptographic algorithm**: An algorithm for performing encipherment or the corresponding algorithm for performing decipherment in which the same key is required for both encipherment and decipherment.
- **3.3.28 trust**: Entity X is said to *trust* entity Y for a set of activities if and only if entity X relies upon entity Y behaving in a particular way with respect to the activities.
- **3.3.29 trusted entity**: An entity that can violate a security policy, either by performing actions which it is not supposed to do, or by failing to perform actions which it is supposed to do.
- **3.3.30 trusted third party**: A security authority or its agent that is trusted with respect to some security-relevant activities (in the context of a security policy).
- 3.3.31 unconditionally trusted entity: A trusted entity that can violate a security policy without being detected.

4 Abbreviations

For the purposes of this Recommendation | International Standard, the following abbreviations apply:

ACI Access Control Information

OSI Open Systems Interconnection

ODP Open Distributed Processing

SI Security Information

TTP Trusted Third Party

iTeh STANDARD PREVIEW

5 Notation

(standards.iteh.ai)

The layer notation used is the same as that defined in ITU-T Rec. X.200 | ISO/IEC 7498-1.

The term service, where not otherwise qualified is used to refer to a security service. 5b-9ac4-

2a6cb35ad728/iso-jec-10181-1-1996

The term certificate, where not otherwise qualified, is used to refer to a security certificate.

6 Organization

The security frameworks are parts of a multi-part International Standard (ISO/IEC 10181) and a series of ITU Recommendations. The security frameworks are described below. Additional security frameworks may be identified in the future. The key management framework is not a part of ISO/IEC 10181, but it has a similar scope and its description is included for completeness.

6.1 Part 1 – Overview

See clause 1.

6.2 Part 2 – Authentication

This framework describes all aspects of authentication as these apply to Open Systems, the relationship of authentication with other security functions such as access control and the management requirements for authentication.

This framework:

- a) defines the basic concepts of authentication;
- b) identifies the possible classes of authentication mechanisms;
- c) defines the services for these classes of authentication mechanism;
- d) identifies functional requirements for protocols to support these classes of authentication mechanism; and
- e) identifies general management requirements for authentication.

4 ITU-T Rec. X.810 (1995 E)

The Authentication Framework occupies a position at the top of a hierarchy of authentication standards that provide concepts, nomenclature and a classification for authentication methods. Directly below it, standards such as ISO/IEC 9798 (Entity Authentication Mechanisms) provide a particular set of these methods in more detail. Finally, at the bottom of the hierarchy, standards such as ITU-T Rec. X.509 | ISO/IEC 9594-8 (the Directory Authentication Framework) use these concepts and methods in the context of a specific application or requirement.

The Authentication Framework describes a model of authentication, a number of phases into which authentication activities can be categorized, the use of a trusted third party, the use of authentication certificates to exchange authentication information, a generic authentication service based on these phases, and at least five classes of authentication mechanism which provide the generic authentication service. These include mechanisms protecting against disclosure of authentication information, and disclosure and replay on the same (and/or different) verifiers.

6.3 Part 3 – Access control

This framework describes all aspects of access control (e.g. user-to-processes, user-to-data, process-to-process, process-to-data) in Open Systems, the relationship to other security functions, such as authentication and audit, and the management requirements for access control.

This framework:

- a) defines the basic concepts for access control;
- demonstrates the manner in which the basic concepts of access control can be specialized to support some commonly recognized access control services and mechanisms;
- c) defines these services and the corresponding access control mechanisms;
- d) identifies functional requirements for protocols to support these access control services and mechanisms;
- e) identifies management requirements to support these access control services and mechanisms;
- f) addresses the interaction of access control services and mechanisms with other security services and mechanisms. ITeh STANDARD PREVIEW

This security framework describes a model of access control, a number of phases into which access control activities can be categorized, a generic access control service based on these phases, and at least three classes of access control mechanism which provide the generic access control service. These include access control lists, capabilities and labels.

6.4 Part 4 – Non-repudiation https://standards.iteh.ai/catalog/standards/sist/a448830c-59ac-465b-9ac4-2a6cb35ad728/iso-iec-10181-1-1996

This framework refines and extends the concepts of the non-repudiation services described in CCITT Rec. X.800 | ISO 7498-2, and provides a framework for the development and provision of these services.

This framework:

- a) defines the basic concepts for non-repudiation;
- b) defines general non-repudiation services;
- c) identifies possible mechanisms to provide the non-repudiation services;
- d) identifies general management requirements for non-repudiation services and mechanisms.

6.5 Part 5 – Confidentiality

The purpose of the confidentiality service is to protect information from unauthorized disclosure. This framework addresses the confidentiality of information in retrieval, transfer and management.

This framework:

- a) defines the basic concepts of confidentiality;
- b) identifies possible classes of confidentiality mechanism;
- c) defines facilities of each class of confidentiality mechanism;
- d) identifies management required to support the classes of confidentiality mechanisms; and
- e) addresses the interaction of the confidentiality mechanism and the supporting services with other security services and mechanisms.

Some of the procedures described in this security framework achieve confidentiality by the application of cryptographic techniques. Use of this framework is not dependent on the use of particular cryptographic or other algorithms, although certain classes of confidentiality mechanism may depend upon particular algorithm properties.
