Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 3.

Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this International Standard may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

International Standard ISO 17357 was prepared by Technical Committee ISO/TC 8, *Ships and marine technology*, Subcommittee SC 9, *General requirements*.

Annex A of this International Standard is for information only.

ITEH STANDARD PREVIEW

Introduction

Throughout this International Standard, the minimum essential criteria are identified by the use of the key word “shall”. Recommended criteria are identified by the use of the key word “should”, and while not mandatory are considered to be of primary importance in providing serviceable, economical and practical connectors. Deviation from the recommended criteria should occur only after careful consideration, extensive testing and thorough service evaluation have shown alternative methods to be satisfactory.

Ships and marine technology — High-pressure floating pneumatic rubber fenders

1 Scope

This International Standard specifies the material, performance and dimensions of high-pressure floating pneumatic rubber fenders, which are intended to be used for the berthing and mooring of a ship to another ship or berthing structure. It also specifies the test and inspection procedures for high-pressure floating pneumatic rubber fenders.

This International Standard does not address any safety hazards associated with its use. It is the user's responsibility to establish appropriate safety and health practices and determine the applicability of regulatory limitations before using this standard.

The documents in the Bibliography provide information on the usage of the fenders.

2 Normative references

The following normative documents contain provisions which, through reference in this text, constitute provisions of this International Standard. For dated references, subsequent amendments to, or revisions of, any of these publications do not apply. However, parties to agreements based on this International Standard are encouraged to investigate the possibility of applying the most recent editions of the normative documents indicated below. For undated references, the latest edition of the normative document referred to applies. Members of ISO and IEC maintain registers of currently valid International Standards.

ISO 12236:1996, *Geotextiles and geotextile-related products — Static puncture test (CBR test)*

3 Terms and definitions

For the purposes of this International Standard, the definitions given in ISO 1382 shall apply, together with the following.

3.1

floating pneumatic rubber fender

fender which is made of synthetic-cord-reinforced rubber sheet with compressed air inside to enable it to float on the water and work as a shock absorber between two ships, or between ships and berthing structures when they come alongside each other on the water

NOTE The fenders have sometimes been colloquially referred to as “Yokohama fenders” or “Yokohama type fenders”. These are examples of suitable products available commercially. This information is given for the convenience of users of this International Standard and does not constitute an endorsement by ISO of these products.

3.2

outer rubber

rubber layer that covers the outside of the fender to protect the cord layers and the inner liner rubber from abrasion and other external forces

3.3

inner rubber

liner of a rubber membrane that seals the pressurized air inside the fender

3.4

synthetic-tyre-cord layer for reinforcement

layer made of synthetic-tyre-cord fabric, which maintains the internal air pressure of the fender

NOTE As the main fibres of the synthetic-tyre-cord fabric are not braided like synthetic canvas fabric or synthetic belt fabric, there are advantages for its fatigue-resistance performance and pressure-holding performance. See annex A.

ITEH STANDARD PREVIEW
(standards.iteh.ai)

3.5

bead ring

steel ring which is placed at one end (or both ends) of the fender and holds the end of cord layers

[ISO 17357:2002](#)

3.6

flange opening

steel flange, which is mounted on the fender, to which an air valve or safety valve can be adapted

<https://standards.iteh.ai/catalog/standards/sist/1b2c9f8e-db92-4085-baa9-58178adc9dbd/iso-17357-2002>

3.7

guaranteed energy absorption

energy that the fender can absorb without permanent deformation or failure

3.8

reaction force

force produced by a fender reacting to a compressive force

NOTE The reactive force is equal to the force of the air pressure of the fender multiplied by the area of the fender in contact with the ship or berthing structure.

3.9

initial internal pressure

air pressure at which an uncompressed fender operates

3.10

endurable pressure

inner pressure at which a fender bursts

3.11

net-type fender

fender which is covered by a protection net consisting of either chain, wire or fibre and usually with tyres or rubber sleeves

3.12

sling-type fender

fender which is designed to be used without a protection net

4 Classification

4.1 Fender types

Fender types are defined as follows:

- a) Type I — net type;
- b) Type II — sling type.

4.2 Initial internal pressure

Initial internal pressures are defined as follows:

- a) pneumatic 50 (initial internal pressure 50 kPa);
- b) pneumatic 80 (initial internal pressure 80 kPa).

5 Ordering information

The fender purchase order, contract or inquiry should state the following.

- The ISO standard number and applicable year, i.e. ISO 17357:2002.

If the purchasers request other sizes, they shall satisfy the requirements of the second paragraph of 6.3.2.

- Fender size: nominal fender diameter and length: see Table 1 or Table 2.
- Fender type: see 4.1.
- Initial internal pressure: see 4.2.
- Fender colour. If not specified, the colour shall be black.
- If a safety valve is required for fenders smaller than 2 500 mm in diameter, see 6.1.7.
- If an identification system is required, see clause 10.
- If inspection/evaluation by a major classification society is required, see clause 12.

6 Requirements

6.1 General fender requirements

6.1.1 Floating pneumatic rubber fenders shall consist of a cylindrical air bag with hemispherical heads at both ends, which shall be filled with compressed air. The basic body construction of this fender shall consist of an outer rubber, synthetic-tyre-cord layers, see annex A, for reinforcement and an inner rubber. All of these shall be vulcanized firmly.

NOTE Alternative reinforcement methods for synthetic-tyre-cord layers may be considered if their strength and durability are designed and proven to be equal to, or superior to, the synthetic-tyre-cord layers after exhaustive trials.

6.1.2 The outer rubber shall protect the cord layers and inner rubber from abrasion and other external forces. This rubber compound shall have sufficient tensile and tear resistance strength to withstand anticipated weather conditions and severe usage. This rubber shall satisfy the values specified in Table 3.

6.1.3 The inner rubber layer shall seal the air inside. This rubber shall satisfy the requirements specified in Table 3.

6.1.4 The reinforcement synthetic-tyre-cord layers shall be strong enough to hold the internal pressure. In both compressed and non-compressed situations, the fender's durable pressure shall be as in Table 4 or Table 5.

6.1.5 The flange opening shall be at either end, or both ends, for convenience of air charge and water filling, if required.

6.1.6 The end of the reinforcement-cord layers shall enter the bead ring and be turned up outside the bead ring, which is built-in at the flange opening. For Type I (net type) fenders, the bead ring and turning up on construction may be excluded.

6.1.7 Fenders of diameter 2 500 mm and larger shall be equipped with a safety valve for releasing excess internal pressure when the fenders are over-compressed accidentally. Fenders which are smaller than 2 500 mm in diameter, can be equipped with a safety valve if required.

6.1.8 The fender shall be equipped with an air valve for inflation and checking air pressure.

6.2 Type requirements

6.2.1 Type I (net type) fenders shall be covered by a chain net, wire net or fibre net. Each end of longitudinal chains, wires or fibres shall be linked together with one or two ring(s), which shall be connected with a guy-chain or guy-rope. Usually, these nets will be fitted with used tyres or rubber sleeves to provide additional protection to the fender body.

6.2.2 Type II (sling type) fenders shall have a lifting device on each end, which shall be connected with a guy-chain or guy-rope.

iTeh STANDARD PREVIEW (standards.iteh.ai)

6.3 Pressure requirements

6.3.1 Pneumatic 50: the internal pressure, durable pressure, safety-valve setting pressure and hydraulic test pressure shall be as specified in Table 4.

[ISO 17357:2002](https://standards.iteh.ai/catalog/standards/sist/1b2c9f8e-db92-4085-baa9-38178ade91bd/iso-17357-2002)

6.3.2 Pneumatic 80: the internal pressure, durable pressure, safety-valve setting pressure and hydraulic test pressure shall be as specified in Table 5.

<https://standards.iteh.ai/catalog/standards/sist/1b2c9f8e-db92-4085-baa9-38178ade91bd/iso-17357-2002>

Sizes not listed in Tables 4 and 5 shall satisfy all the requirements in this subclause, using the pressure requirements of the next-larger-diameter size. (Example: a 2 200 mm diameter fender shall satisfy the pressure requirements of a 2 500 mm diameter fender.)

7 Performance

7.1 Specification of performance

The performance of floating pneumatic rubber fenders shall be specified in terms of guaranteed energy absorption (GEA), reaction force at GEA deflection, and hull pressure at GEA deflection.

7.2 Performance curves

The relationship between the deflection percentage, reaction force, inner pressure (which is equal to the hull pressure) and energy absorption is shown in Figure 1. The reaction force, the inner pressure and the energy absorption of the fender increase as the deflection percentage increases. From the GEA value, point A is determined on the energy absorption curve and the corresponding deflection percentage is read as the GEA deflection. The reaction force and the hull pressure are then obtained at that deflection percentage value.

7.3 Fender performance

7.3.1 Pneumatic 50: the fenders shall comply with the values specified in Table 1.

7.3.2 Pneumatic 80: The fenders shall comply with the values specified in Table 2.

7.3.3 Guaranteed energy absorption (GEA) values shown in Table 1 or Table 2 shall be obtained at $60 \pm 5\%$ deflection.

7.3.4 The tolerance of reaction force at the GEA deflection shall be $\pm 10\%$.

7.3.5 Fender performance can be calculated by the formula, which shall be established using the performance test described in 8.1.

8 Performance confirmation of prototype fender test

8.1 General

Each fender, involving different methods of basic construction and/or design, shall require a prototype test.

Fenders of lesser diameter than a prototype confirmed fender, incorporating the same basic design, construction and fabrication methods but having fewer plies due to the smaller diameter, but satisfying all requirements of this International Standard, do not require a prototype test.

8.2 Performance test, parallel compression test

8.2.1 To determine the performance of the fenders given in clause 7, a performance test shall be performed. Applying a compressive force perpendicularly to the fender, the fender shall be compressed until its energy absorption reaches the guaranteed energy absorption (GEA) value. The compression speed shall not exceed 80 mm/min. The reaction force and internal pressure shall be recorded at least every 5 % percentage deflection. The percentage deflection, y , and the energy absorption, a , are calculated as follows.

$$y = \frac{L_c}{D} \times 100 \quad (1)$$

where

y is the percentage deflection;

L_c is the compression length, in millimetres;

D is the original diameter, in millimetres (i.e. the fender diameter at initial pressure).

$$a = \int R(x) dx \quad (2)$$

where

$R(x)$ is the reaction at a given deflection;

dx is the incremental deflection.

The test shall be repeated twice with an interval of 5 min between the two tests. The energy absorption and the reaction force shall be obtained from the mean value of the two test records.

A fender meets the required GEA performance if it achieves 100 % of its GEA energy absorption without exceeding 65 % deflection and 110 % of its GEA reaction.
