

Designation: F 748 - 04

# Standard Practice for Selecting Generic Biological Test Methods for Materials and Devices<sup>1</sup>

This standard is issued under the fixed designation F 748; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon ( $\epsilon$ ) indicates an editorial change since the last revision or reapproval.

#### 1. Scope

- 1.1 This practice recommends generic biological test methods for materials and devices according to end-use applications. While chemical testing for extractable additives and residual monomers or residues from processing aids is necessary for most implant materials, such testing is not included as part of this practice. The reader is cautioned that the area of materials biocompatibility testing is a rapidly evolving field, and improved methods are evolving rapidly, so this practice is by necessity only a guideline. A thorough knowledge of current techniques and research is critical to a complete evaluation of new materials.
- 1.2 These test protocols are intended to apply to materials and medical devices for human application. Biological evaluation of materials and devices, and related subjects such as pyrogen testing, batch testing of production lots, and so on, are also discussed. Tests include those performed on materials, end products, and extracts. Rationale and comments on current state of the art are included for all test procedures described.
- 1.3 The biocompatibility of materials used in single or multicomponent medical devices for human use depends to a large degree on the particular nature of the end-use application. Biological reactions that are detrimental to the success of a material in one device application may have little or no bearing on the successful use of the material for a different application. It is, therefore, not possible to specify a set of biocompatibility test methods which will be necessary and sufficient to establish biocompatibility for all materials and applications.
- 1.4 The ethical use of research animals places the obligation on the individual investigator to determine the most efficient methods for performing the necessary testing without undue use of animals. Where adequate prior data exists to substantiate certain types of safety information, these guidelines should not be interpreted to mean that testing should be unnecessarily repeated.
- 1.5 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the

responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

### 3. Summary of Practice

3.1 A matrix listing biological test methods versus materials (devices) and their applications is included in Table 1. The expected duration of use of the device is also considered. Intraoperative is less than 24 h, short-term is up to and including 30 days, chronic is greater than 30 days. The position of row and column intersection is marked to indicate whether the test is recommended for a material or device for the specific application indicated. The terms relating to device or material type and application are addressed in Section 5. Discussion of applicability, current state of the art, and rationale for individual test methods also appears in that section.

#### 4. Significance and Use

- 4.1 The objective of this practice is to recommend sufficient biological testing to establish a reasonable level of confidence concerning the biological response to a material or device, while at the same time avoiding unnecessary testing.
- 4.2 This practice is intended to provide guidance to the materials investigator in selecting the proper procedures to be carried out for the screening of new or modified materials. Because each material and each implant situation involves its own unique circumstances, these recommendations should be modified as necessary and do not constitute the only testing that will be required for a material nor should these guidelines be interpreted as minimum requirements for any particular situation. While an attempt has been made to provide recommendation for different implant circumstances, some of the recommended testing may not be necessary or reasonable for a specific material or application.

## 5. Classification of Materials and Devices by End-Use Applications

- 5.1 General:
- 5.1.1 When new materials are sought for a medical application for use on humans, the material(s) may comprise the whole final device product, or may be one of many component materials in the device. The first step is a thorough literature search for previous use of the material or biocompatibility testing studies to ensure that it has not been known to produce an adverse biological response that exceeds the expected benefit in the use of the device. Note that the final fabricated product may differ chemically, physically, or biologically from the raw materials used to fabricate the product due to processing and this has to be considered when designing test protocols. For some devices, it may be necessary or desirable to take material test samples directly from the final device product. Samples should be fully representative of the finished product in terms of processing, cleaning, packaging, sterilization, and any other procedures that are performed on the materials before the device is used.
- 5.1.2 At this point, preliminary material screening may be employed, depending on the expertise of the organizations evaluating the materials. Since preliminary screening is normally an option to minimize the economic impact of a candidate material failing final biological tests after extensive time and effort, it is not a required procedure. The investigator should be aware that, should an adverse tissue response be observed with a final product, it may be impossible to determine which component or process is responsible without these initial screening tests.
- 5.1.3 This practice addresses two dimensions of tissue-material interactions: duration and tissue type. A third dimension, which should be considered, is the relative size difference between the host and the material, that is, to how much material surface area is the host exposed. The material surface area to body weight ratio may become a significant factor for porous materials, and devices of repeated short-term applications (for example, dialysis products). While this practice does not address the issue of "intensity factor" of increased surface
