Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of technical committees is to prepare International Standards. Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

ISO 22009 was prepared by Technical Committee ISO/TC 20, *Aircraft and space vehicles*, Subcommittee SC 14, *Space systems and operations*.

Introduction

This International Standard describes the main requirements to the earth's magnetospheric magnetic field model. The model satisfying the set of requirements is described in Annex A as example calculations. The model can be used in scientific and engineering applications and is intended to calculate the magnetic induction field generated from a variety of current systems located on the boundaries and within the boundaries of the earth's magnetosphere under a wide range of environmental conditions, quiet and disturbed, that are affected by solar-terrestrial interactions stimulated by solar activity such as solar flares and related phenomena, which induce terrestrial magnetic disturbances such as magnetic storms.

Space systems — Space environment (natural and artificial) — Model of the earth's magnetospheric magnetic field

1 Scope

This International Standard describes the main magnetospheric large-scale current systems and the magnetic field in the earth's magnetosphere and provides the main requirements for a model of the magnetospheric magnetic field. Ionospheric currents are not considered in this International Standard. Annex A of this International Standard gives a worked example of the model and establishes the parameters of magnetospheric large-scale current systems that change according to conditions in the space environment. This International Standard can be used to develop new models of the magnetospheric magnetic field. Such models are useful in investigating the physical processes in the earth's magnetosphere as well as in calculations associated with developing, testing and estimating the results of exploitation of spacecrafts and other equipment operating in the space environment.

The main goals of standardizing the concepts of the earth's magnetospheric magnetic field are to provide

- an unambiguous presentation of the magnetic field in the earth's magnetosphere;
- compatibility for the results of the interpretation and analysis of space experiments;
- less labour-intensive calculations of the magnetic field of magnetospheric currents in space at geocentric distances of 1,0 to 6,6 earth radii, R_E ;
- the most reliable calculations of all elements of the geomagnetic field in the space environment.

The magnetic field model presented in Annex A of this International Standard can be used to predict the radiation conditions in space, including the periods of intense magnetic disturbances (magnetic storms), when developing systems of spacecraft magnetic orientation and when forecasting the influence of magnetic disturbances on transcontinental piping and power transmission lines.

2 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

2.1

internal magnetic field

⟨main magnetic field⟩ magnetic field produced by the sources inside the earth's core

NOTE It can be presented in the form of a series of spherical harmonic functions. The expansion coefficients [International Geomagnetic Reference Field (IGRF) model] undergo very slight changes in time. The International Association of Geomagnetism and Aeronomy (IAGA) is responsible for IGRF model development and modifications and approves its coefficients every five years. Internal magnetic field is not addressed by this International Standard.

2.2

external magnetic field

⟨magnetospheric magnetic field⟩ magnetic field produced by magnetospheric sources of magnetic field

2.3 magnetospheric sources of magnetic field

sources of magnetic fields including the following:

- currents flowing over the magnetopause and screening the geomagnetic dipole magnetic field;
- currents flowing inside the earth's magnetosphere, including
 - tail currents, produced by currents across the geomagnetic tail and closure currents on the magnetopause,
 - ring currents, including symmetrical ring current, circling around the earth and carried by trapped particles and partial ring current, produced by azimuthal currents at low latitudes flowing mostly in the pre-midnight sector, and closed by field-aligned and ionospheric currents,
 - field-aligned currents, produced by currents flowing along the high-latitude magnetic field lines, closed by currents on the magnetopause and in the ionosphere;
- currents flowing over the magnetopause and screening the ring current and partial ring current magnetic fields

NOTE 1 Electric currents flowing entirely in the ionosphere (ionospheric currents) contribute to the magnetic field variation at altitudes below 1 000 km. In the region above 1,5 R_E , the effect of the ionospheric current is insignificant.

NOTE 2 Magnetic field of ionospheric currents is not addressed by this International Standard.

2.4 geomagnetic dipole tilt angle
angle of inclination of the geomagnetic dipole to the plane orthogonal to the earth-sun line

2.5 solar-magnetospheric (GSM) coordinates

Cartesian geocentric coordinates, where the X-axis is directed to the sun, the Z-axis, which is orthogonal to the X-axis, lies on the plane with the X-axis and the geomagnetic dipole axis, and the Y-axis supplements the X-and Z-axes to the right-hand system

2.6 magnetopause stand-off distance

geocentric distance to the subsolar point on the magnetopause

3 General concepts and assumptions

3.1 Magnetic field induction in the earth's magnetosphere

The vector, \vec{B}_M , expressed in nanoteslas, of the magnetic field induction in the earth's magnetosphere is calculated from Equation (1):

$$\vec{B}_M = \vec{B}_1 + \vec{B}_2 \tag{1}$$

where

\vec{B}_1 is the vector of induction of the internal magnetic field;

\vec{B}_2 is the vector of induction of the external magnetospheric magnetic field.

The magnetic field of the magnetospheric currents (external magnetic field), \vec{B}_2 , is calculated in terms of the quantitative model of the magnetosphere.

3.2 Magnetospheric magnetic field standardization: process-based approach

This International Standard for magnetospheric magnetic fields does not specify a single magnetospheric model, theoretical or empirical. In order to encourage continual improvements in magnetospheric modelling, this International Standard is a process-based standard for determining the magnetospheric magnetic field. The magnetospheric magnetic field model, after its development, can satisfy the requirements in Clause 4 and the list of criteria presented in Clause 5. The worked example of the model is presented in Annex A and it is necessary that it be reconsidered every five years relative to the candidate models. The current worked example is presented in the Annex A.

4 Model requirements

4.1 General

The model of the magnetic field of magnetospheric currents (subsequently referred to as the “model”) presents the vector of induction of magnetospheric currents in solar-magnetospheric coordinates.

The model describes a regular part of the magnetic field in the region from $1,0 R_E$ to $6,6 R_E$.

The model reflects the compression of the earth's magnetosphere in the dayside due to interaction with the solar wind, day-night asymmetry (i.e. the field on the nightside is weakened), daily and seasonal variations.

The model takes into account the geomagnetic dipole tilt angle, varying in the range from -35° to $+35^\circ$.

4.2 Magnetospheric magnetic field sources

The standardized magnetospheric magnetic field is produced by the currents described in 2.3. The effect of the ionospheric currents is not addressed by this International Standard.

<https://standards.iteh.ai/catalog/standards/sist/47798206-7a0f-449f-a5c3-3059d21c752a/iso-22009-2009>

4.3 Parameterization

Each magnetospheric source of magnetic field depends on parameters that are calculated from empirical data.

4.4 Magnetospheric dynamics

The magnetospheric dynamics is determined from a sequence of its instantaneous states.

4.5 Model testing and comparison with measurements

The model testing is carried out with the help of databases that include spacecraft-based and on-ground measurements. The dataset used for the model testing is presented in Annex C.

5 List of criteria

The compliance criteria for this International Standard consist of the activities common for any candidate magnetospheric magnetic field model. These criteria specify the compliance process that includes the documentation, publication and testing of the model and include the following.

- The candidate model shall include a statement of the modeling approach used (empirical or theoretical model). The empirical models shall include a clear specification of the input data used to derive the model and where these data were measured. Theoretical models shall include a description of the physical principles and approaches that are used as the basis of the model.

- A statement concerning the candidate model area of application and domain of applicability should be included.
- A statement about the root-mean-square (rms) errors during the model calculations relative to the deviations from the observational data obtained from measurements should be included. For empirical models, comparisons should also be made with data, different from those on which the model is based.
- A description and implementation of the magnetospheric magnetic field model should be published in internationally accessible, refereed journals.

<https://standards.iteh.ai/catalog/standards/sist/47798206-7a0f-449f-a5c3-3059d21c752a/iso-22009-2009>

Annex A (informative)

Paraboloid model of the magnetospheric magnetic field: calculation of induction of the magnetic field of the magnetospheric currents

A.1 Paraboloid model of the magnetic field of magnetospheric currents

A.1.1 General

The magnetospheric magnetic field calculated by paraboloid model is a solution of the magnetostatic problem inside the paraboloid of revolution.

The vector of induction of the magnetic field of magnetospheric currents is calculated from Equation (A.1):

$$\vec{B}_2 = \vec{B}_{sd}(\psi, R_1) + \vec{B}_t(\psi, R_1, R_2, \Phi_\infty) + \vec{B}_r(\psi, b_t) + \vec{B}_{sr}(\psi, R_1, b_r) + \vec{B}_{fac}(I_0) \quad (\text{A.1})$$

where

\vec{B}_{sd} is the magnetic field of currents on the magnetopause screening the dipole field;

\vec{B}_t is the magnetic field of the magnetospheric tail;

\vec{B}_r is the magnetic field of the ring current;

\vec{B}_{sr} is the magnetic field of currents on the magnetopause, screening the ring current field;

\vec{B}_{fac} is the magnetic field of region 1 field-aligned currents.

The components of the magnetic field of magnetospheric currents, \vec{B}_{sd} , \vec{B}_t , \vec{B}_r , \vec{B}_{sr} and \vec{B}_{fac} are calculated separately in terms of the paraboloid model of the magnetosphere in the form of series in the Bessel functions or Legendre polynomials.

A.1.2 Parameters

The components of the magnetic field of magnetospheric currents, \vec{B}_{sd} , \vec{B}_t , \vec{B}_r , \vec{B}_{sr} and \vec{B}_{fac} are determined from the values of the following parameters of the magnetospheric current systems:

ψ is the geomagnetic dipole tilt angle, expressed in degrees;

\vec{R}_1 is the distance to the subsolar point at the magnetopause, expressed in earth radii;

\vec{R}_2 is the distance to the earthward edge of the magnetospheric tail current sheet, expressed in earth radii;

Φ_∞ is the magnetic flux in the tail lobes, defining the current intensity in the magnetotail, expressed in webers;
