

Designation: D 698–00 Designation: D 698 – $07^{\epsilon 1}$

Standard Test Methods for Laboratory Compaction Characteristics of Soil Using Standard Effort (12,400(12 400 ft-lbf/ft³ (600 kN-m/m³))¹

This standard is issued under the fixed designation D 698; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

ε¹ Note—Figure 2 was editorially corrected in July 2007.

1. Scope*

1.1This 1.1 These test methods covers laboratory compaction procedures methods used to determine the relationship between molding water content and dry unit weight of soils (compaction curve) compacted in a 4 or 6-in. (101.6 or 152.4-mm) diameter mold with a 5.50-lbf (24.45-N) rammer dropped from a height of 12.0 in. (305 mm) producing a compactive effort of 12,400 ft-lbf/ft³ (600 kN-m/m³).

Note 1—The equipment and procedures are similar as those proposed by R. R. Proctor (*Engineering News Record*—September 7, 1933) with this one major exception: his rammer blows were applied as "12 inch firm strokes" instead of free fall, producing variable compactive effort depending on the operator, but probably in the range 15,000 to 25,000 to 25,000 ft-lbf/ft³(700 to 1,200 kN-m/m). The standard effort test (see 3.2.23.1.3) is sometimes referred to as the Proctor Test. Note2—Soils and soil-aggregate mixtures should be regarded as natural occurring fine- or coarse-grained soils or composites or mixtures of natural soils, or mixtures of natural and processed soils or aggregates such as silt, gravel, or crushed rock.

1.2This test method applies only to soils that have 30% or less by weight of particles retained on the 3/4-inch (19.0-mm) sieve.

Note3—For relationships between unit weights and water contents of soils with 30% or less by weight of material retained on the ¾-in. (19.0-mm) sieve to unit weights and water contents of the fraction passing ¾

- 1.1.1 Soils and soil-aggregate mixtures are to be regarded as natural occurring fine- or coarse-grained soils, or composites or mixtures of natural soils, or mixtures of natural and processed soils or aggregates such as gravel or crushed rock. Hereafter referred to as either soil or material.
- 1.2 These test methods apply only to soils (materials) that have 30 % or less by mass of particles retained on the ³/₄-in. (19.0-mm) sieve and have not been previously compacted in the laboratory; that is, do not reuse compacted soil.
- 1.2.1 For relationships between unit weights and molding water contents of soils with 30 % or less by mass of material retained on the ¾-in. (19.0-mm) sieve to unit weights and molding water contents of the fraction passing ¾-in. (19.0-mm) sieve, see Practice D 4718D4718.
- 1.3 Three alternative <u>procedures</u> are provided. The <u>proceduremethod</u> used shall be as indicated in the specification for the material being tested. If no <u>proceduremethod</u> is specified, the choice should be based on the material gradation.
 - 1.3.1 *Procedure A*Method A:
 - 1.3.1.1 *Mold*—4-in. (101.6-mm) diameter.
 - 1.3.1.2 Material—Passing No. 4 (4.75-mm) sieve.
 - 1.3.1.3 Layers—Three.
 - 1.3.1.4 *Blows per layer*Blows per Layer—25.
- 1.3.1.5 *Usage*—May be used if 20%25% or less (see Section 1.4) by weightmass of the material is retained on the No. 4 (4.75-mm) sieve.
- 1.3.1.6 Other Use—If this procedure is not specified, materials that meet these gradation requirements may be tested using Procedures B or C. Other Usage—If this gradation requirement cannot be met, then Method C may be used.
 - 1.3.2 *Procedure B*Method B:
 - 1.3.2.1 Mold—4-in. (101.6-mm) diameter.
 - 1.3.2.2 Material—Passing 3/8-in. (9.5-mm) sieve.
 - 1.3.2.3 Layers—Three.
 - 1.3.2.4 Blows per layerBlows per Layer—25.

Current edition approved March 10, 2000. Published August 2000. Originally published as D 698–91. Last previous edition D 698–91 (1998). Current edition approved April 15, 2007. Published July 2007. Originally approved in 1942. Last previous edition approved in 2000 as D 698 – 00a^{c1}.

¹ This test method_standard is under the jurisdiction of ASTM Committee D18 on Soil and Rock and is the direct responsibility of Subcommittee D18.03 on Texture, Plasticity and Density Characteristics of Soils.

- 1.3.2.5 *Use*—Shall be used if more than 20% by weight of the material is retained on the No. 4 (4.75-mm) sieve and 20% or less by weight of the material is retained on the ³½-Usage—May be used if 25 % or less (see Section 1.4) by mass of the material is retained on the ³½-in. (9.5-mm) sieve.
- 1.3.2.6 Other Use—If this procedure is not specified, materials that meet these gradation requirements may be tested using Procedure C. Other Usage—If this gradation requirement cannot be met, then Method C may be used.
 - 1.3.3 *Procedure C*Method C:
 - 1.3.3.1 *Mold*—6-in. (152.4-mm) diameter.
 - 1.3.3.2 *Material*—Passing ³/₄-inch (19.0-mm) sieve. -in. (19.0-mm) sieve.
 - 1.3.3.3 Layers—Three.
 - 1.3.3.4 Blows per layer—56.
- 1.3.3.5 *Use*—Shall be used if more than 20% by weight of the material is retained on the ¾-in. (9.5-mm) sieve and less than 30% by weight of the material is retained on the ¾-Usage—May be used if 30 % or less (see Section 1.4) by mass of the material is retained on the ¾-in. (19.0-mm) sieve.
 - 1.3.4 The 6-in. (152.4-mm) diameter mold shall not be used with ProcedureMethod A or B.
- Note 42—Results have been found to vary slightly when a material is tested at the same compactive effort in different size molds, with the smaller mold size typically yielding larger values of density/unit weight (1, pp. 21+).
- 1.4 If the test specimen contains more than 5 % by weight mass of oversize fraction (coarse fraction) and the material will not be included in the test, corrections must be made to the unit weightmass and molding water content of the specimen or to the appropriate field-in-place density test specimen using Practice D 4718D4718.
- 1.5 This test method will generally produce a well-defined maximum dry unit weight for non-free draining soils. If this test method is used for free-draining soils the maximum unit weight may not be well defined, and can be less than obtained using Test Methods D 4253D4253.
- 1.6The values in inch-pound units are to be regarded as the standard. The values stated in SI units are provided for information only.
- 1.6.1In the engineering profession it is customary practice to use, interchangeably, units representing both mass and force, unless dynamic calculations (F=Ma) are involved. This implicitly combines two separate systems of units, that is, the absolute system and the gravimetric system. It is scientifically undesirable to combine the use of two separate systems within a single standard. This test method has been written using inch-pound units (gravimetric system) where the pound (lbf) represents a unit of force. The use of mass (lbm) is for convenience of units and is not intended to convey the use is scientifically correct. Conversions are given in the SI system in accordance with IEEE/ASTM SI 10IEEE/ASTM SI 10. The use of balances or scales recording pounds of mass (lbm), or the recording of density in lbm/ft
- 1.6 All observed and calculated values shall conform to the guidelines for significant digits and rounding established in Practice D 6026D6026, unless superseded by this standard.
- 1.6.1 For purposes of comparing measured or calculated value(s) with specified limits, the measured or calculated value(s) shall be rounded to the nearest decimal or significant digits in the specified limits.
- 1.6.2 The procedures used to specify how data are collected/recorded or calculated, in this standard are regarded as the industry standard. In addition, they are representative of the significant digits that generally should be retained. The procedures used do not consider material variation, purpose for obtaining the data, special purpose studies, or any considerations for the user's objectives; and it is common practice to increase or reduce significant digits of reported data to be commensurate with these considerations. It is beyond the scope of this standard to consider significant digits used in analytical methods for engineering design.
- 1.7 The values in inch-pound units are to be regarded as the standard. The values stated in SI units are provided for information only, except for units of mass. The units for mass are given in SI units only, g or kg.
- 1.7.1 It is common practice in the engineering profession to concurrently use pounds to represent both a unit of mass (lbm) and a force (lbf). This implicitly combines two separate systems of units; that is, the absolute system and the gravitational system. It is scientifically undesirable to combine the use of two separate sets of inch-pound units within a single standard. This standard has been written using the gravitational system of units when dealing with the inch-pound system. In this system, the pound (lbf) represents a unit of force (weight). However, the use of balances or scales recording pounds of mass (lbm) or the recording of density in lbm/ft should shall not be regarded as a nonconformance with this standard.
- 1.71.8 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3. Terminology

3.1 Definitions: See Terminology D 653D 653 for general definitions.

3.2Description of Terms Specific to This Standard:

3.2.1oversize fraction (coarse fraction), P_c in %—the portion of total sample not used in performing the compaction test; it may be the portion of total sample retained on the No. 4 (4.75-mm), %-in. (9.5-mm), or ¾-in. (19.0-mm) sieve.

3.2.2

3.1 *Definitions*—See Terminology D 653D653 for general definitions.

3.1.1 molding water content, n—the adjusted water content of a soil (material) that will be compacted/reconstituted. 3.1.2 standard effort—the term for the 12,400 ft-lbf/ft—in compaction testing, the term for the 12 400 ft-lbf/ft (600 kN-m/m 3) compactive effort applied by the equipment and proceduresmethods of this test.

 $3.2.3\underline{3.1.3}$ standard maximum dry unit weight, $\gamma_{\text{clmaxd},max}$ in lbf/ft³(kN/m³)—the maximum value defined by the compaction curve for a compaction test using standard effort.

3.2.4standard optimum water content, w_a in %—the water content at which a soil can be compacted to the maximum dry unit weight using standard compactive effort.

3.2.5—in compaction testing, the maximum value defined by the compaction curve for a compaction test using standard effort.

3.1.4 standard optimum water content, w_{opt} in %—in compaction testing, the molding water content at which a soil can be compacted to the maximum dry unit weight using standard compactive effort.

3.2 Definitions of Terms Specific to This Standard:

³ For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For Annual Book of ASTM Standards , Vol 04.08. volume information, refer to the standard's Document Summary page on the ASTM website.

- 3.2.1 oversize fraction (coarse fraction), P_C in %—the portion of total specimen not used in performing the compaction test; it may be the portion of total specimen retained on the No. 4 (4.75-mm) sieve in Method A, $\frac{3}{8}$ -in. (9.5-mm) sieve in Method B, or $\frac{3}{4}$ -in. (19.0-mm) sieve in Method C.
- <u>3.2.2</u> test fraction (finer fraction), P_F in % —the portion of the total <u>sample specimen</u> used in performing the compaction test; it is the fraction passing the No. 4 (4.75-mm) sieve in <u>Procedure Method</u> A, <u>minus-passing the</u> $\frac{3}{4}$ -in. (9.5-mm) sieve in <u>Procedure Method</u> C.

4. Summary of Test Method

4.1 A soil at a selected <u>molding</u> water content is placed in three layers into a mold of given dimensions, with each layer compacted by 25 or 56 blows of a 5.50-lbf (24.47-N) rammer dropped from a distance of 12-in. (305-mm), 12.00 in. (304.8 mm), subjecting the soil to a total compactive effort of about 12,40012 400 ft-lbf/ft³ (600 kN-m/m³). The resulting dry unit weight is determined. The procedure is repeated for a sufficient number of <u>molding</u> water contents to establish a relationship between the dry unit weight and the <u>molding</u> water content for the soil. This data, when plotted, represents a curvilinear relationship known as the compaction curve. The values of optimum water content and standard maximum dry unit weight are determined from the compaction curve.

5. Significance and Use

- 5.1 Soil placed as engineering fill (embankments, foundation pads, road bases) is compacted to a dense state to obtain satisfactory engineering properties such as, shear strength, compressibility, or permeability. Also, In addition, foundation soils are often compacted to improve their engineering properties. Laboratory compaction tests provide the basis for determining the percent compaction and molding water content needed to achieve the required engineering properties, and for controlling construction to assure that the required compaction and water contents are achieved.
- 5.2 During design of an engineered fill, shear, consolidation, permeability, or other tests require preparation of test specimens by compacting at some <u>molding</u> water content to some unit weight. It is common practice to first determine the optimum water content (w_{opt}) and maximum dry unit weight $(\gamma_{d,max})$ by means of a compaction test. Test specimens are compacted at a selected <u>molding</u> water content (w), either wet or dry of optimum (w_{opt}) or at optimum (w_{opt}) , and at a selected dry unit weight related to a percentage of maximum dry unit weight $(\gamma_{d,max})$. The selection of <u>molding</u> water content (w), either wet or dry of optimum (w_{opt}) or at optimum (w_{opt}) and the dry unit weight $(\gamma_{d,max})$ may be based on past experience, or a range of values may be investigated to determine the necessary percent of compaction.
- 5.3Experience indicates that the methods outlined in 5.2 or the construction control aspects discussed in 5.1 are extremely difficult to implement or yield erroneous results when dealing with certain soils. 5.3.1-5.3.3 describe typical problem soils, the problems encountered when dealing with such soils and possible solutions for these problems.
- 5.3.1 Oversize Fraction—Soils containing more than 30 % oversize fraction (material retained on the ¾-in. (19-mm) sieve) are a problem. For such soils, there is no ASTM test method to control their compaction and very few laboratories are equipped to determine the laboratory maximum unit weight (density) of such soils (USDI Bureau of Reclamation, Denver, CO and U.S. Army Corps of Engineers, Vicksburg, MS). Although Test Methods D 4914D4914 and D 5030D5030 determine the "field" dry unit weight of such soils, they are difficult and expensive to perform.
- 5.3.1.1 One method to design and control the compaction of such soils is to use a test fill to determine the required degree of compaction and the method to obtain that compaction, followed by use of a method specification to control the compaction. Components of a method specification typically contain the type and size of compaction equipment to be used, the lift thickness, acceptable range in molding water content, and the number of passes.
- Note 53—Success in executing the compaction control of an earthwork project, especially when a method specification is used, is highly dependent upon the quality and experience of the "contractor" contractor and "inspector." inspector.
- 5.3.1.2 Another method is to apply the use of density correction factors developed by the USDI Bureau of Reclamation (1,(2,3)) and U.S. Corps of Engineers (3(4)). These correction factors may be applied for soils containing up to about 50 to 70 % oversize fraction. Each agency uses a different term for these density correction factors. The USDI Bureau of Reclamation uses D ratio (or D-VALUE), while the U.S. Corps of Engineers uses Density Interference Coefficient (I_c).
- 5.3.1.3 The use of the replacement technique (Test Method D 698–78, Method D), in which the oversize fraction is replaced with a finer fraction, is inappropriate to determine the maximum dry unit weight, $\gamma_{\text{dmax}} d, \text{max}$, of soils containing oversize fractions (3(4)).
- 5.3.2 *Degradation*—Soils containing particles that degrade during compaction are a problem, especially when more degradation occurs during laboratory compaction than field compaction, as is typical. Degradation typically occurs during the compaction of a granular-residual soil or aggregate. When degradation occurs, the maximum dry-unit weight increases (41), p. 73) so that the laboratory maximum value is not representative of field conditions. Often, in these cases, the maximum dry unit weight is impossible to achieve in the field.
- 5.3.2.1 Again, for soils subject to degradation, the use of test fills and method specifications may help. Use of replacement techniques is not correct.
- 5.3.3 *Gap Graded*—Gap-graded soils (soils containing many large particles with limited small particles) are a problem because the compacted soil will have larger voids than usual. To handle these large voids, standard test methods (laboratory or field)

typically have to be modified using engineering judgement.

Note 4—The quality of the result produced by this standard is dependent on the competence of the personnel performing it, and the suitability of the equipment and facilities used. Agencies that meet the criteria of Practice D 3740D3740 are generally considered capable of competent and objective testing/sampling/inspection, and the like. Users of this standard are cautioned that compliance with Practice D 3740D3740 does not in itself assure reliable results. Reliable results depend on many factors; Practice D 3740D3740 provides a means of evaluating some of those factors.

6. Apparatus

- 6.1 *Mold Assembly*—The molds shall be cylindrical in shape, made of rigid metal and be within the capacity and dimensions indicated in 6.1.1 or 6.1.2 and Fig. 1Figs. 1 and and Fig. 22. See also Table 1. The walls of the mold may be solid, split, or tapered. The "split" type may consist of two half-round sections, or a section of pipe split along one element, which can be securely locked together to form a cylinder meeting the requirements of this section. The "tapered" type shall have an internal diameter taper that is uniform and not more than 0.200 in./ft (16.7-(16.7 mm/m)) of mold height. Each mold shall have a base plate and an extension collar assembly, both made of rigid metal and constructed so they can be securely attached and easily detached from the mold. The extension collar assembly shall have a height extending above the top of the mold of at least 2.0 in. (50.8-mm) (51 mm) which may include an upper section that flares out to form a funnel, provided there is at least a 0.75 in. (19.0-mm) (19 mm) straight cylindrical section beneath it. The extension collar shall align with the inside of the mold. The bottom of the base plate and bottom of the centrally recessed area that accepts the cylindrical mold shall be planar within ±0.005 in. (±0.1 mm).
- 6.1.1 *Mold*, 4 in.—A mold having a 4.000 \pm 0.016-in. (101.6 \pm 0.4-mm) average inside diameter, a height of 4.584 \pm 0.018-in. (0.018 in. (116.4 \pm 0.5-mm) 0.5 mm) and a volume of 0.0333 \pm 0.0005 ft³(944 (943.0 \pm 14 cm³). A mold assembly having the minimum required features is shown in Fig. 1.
- 6.1.2~Mold, 6~in.—A mold having a 6.000 ± 0.026 -in. (152.4 ± 0.7 -mm) average inside diameter, a height of 4.584 ± 0.018 -in. 0.018~in. (116.4 ± 0.5 -mm), 0.5~mm), and a volume of $0.0750 \pm 0.0009~ft^3$ ($2124 \pm 25~cm^3$). A mold assembly having the minimum required features is shown in Fig. 2.
- 6.2 Rammer—A rammer, either manually operated as described further in 6.2.1 or mechanically operated as described in 6.2.2. The rammer shall fall freely through a distance of 12.00 ± 0.05 -in. 0.05 in. 0.05 in. 0.05 in. 0.04 in. 0.05 in. 0.

Note6—It is a common and acceptable practice in the inch-pound system to assume that the mass of the rammer is equal to its mass determined using either a kilogram or pound balance and 1 lbf is equal to 1 lbm or 0.4536 kg. or 1 N is equal to 0.2248 lbm or 0.1020 kg.

- 6.2.1 5—It is a common and acceptable practice to determine the weight of the rammer using either a kilogram or pound balance and assume 1 lbf is equivalent to 0.4536 kg, 1 lbf is equivalent to 1 lbm, or 1 N is equivalent to 0.2248 lbf or 0.1020 kg.
- <u>6.2.1</u> Manual Rammer—The rammer shall be equipped with a guide sleeve that has sufficient clearance that the free fall of the rammer shaft and head is not restricted. The guide sleeve shall have at least four vent holes at each end (eight holes total) located with centers $\frac{3}{4} \pm \frac{1}{16} \frac{1}{\sin (9.5 + \text{mm})} = \frac{1.6 + \text{mm}}{2 + \text{mm}}$ from each end and spaced 90 degrees apart. The minimum diameter of the vent holes shall be $\frac{3}{8 + \text{in}} = \frac{9.5 + \text{mm}}{1.0 + \text{mm}}$. Additional holes or slots may be incorporated in the guide sleeve.
- 6.2.2 Mechanical Rammer-Circular Face— The rammer shall operate mechanically in such a manner as to provide uniform and complete coverage of the specimen surface. There shall be 0.10 ± 0.03 -in. $(2.5 \pm 0.8$ -mm) clearance between the rammer and the inside surface of the mold at its smallest diameter. The mechanical rammer shall meet the standardization/calibration requirements of Test Methods D 2168D2168. The mechanical rammer shall be equipped with a positive mechanical means to support the rammer when not in operation.
 - 6.2.2.1 Mechanical Rammer-Sector Face—When— The sector face shall be used with the 6-in. (152.4-mm) mold, a sector face

rammer may be used in place of the circular face rammer. The specimen contact striking face shall have the shape of a sector of a circle of radius equal to 2.90 ± 0.02 -in. 0.02-in. 0.02-in.

- 6.3 Sample Extruder (optional)—A jack, with frame or other device adapted for the purpose of extruding compacted specimens from the mold.
- 6.4 Balance—A class GP5 balance meeting the requirements of Specification D 4753D 4753 for a balance of 1-g readability.—A Class GP5 balance meeting the requirements of Specification D 4753D4753 for a balance of 1-g readability. If the water content of the compacted specimens is determined using a representative portion of the specimen, rather than the whole specimen, and if the representative portion is less than 1000 g, a Class GP2 balance having a 0.1-g readability is needed in order to comply with Test Methods D 2216D2216 requirements for determining water content to 0.1 %.

Note 6—Use of a balance having an equivalent capacity and a readability of 0.002 lbm as an alternative to a class GP5 balance should not be regarded as nonconformance to this standard.

- 6.5 Drying Oven—Thermostatically controlled, preferably of a forced-draft type and capable of maintaining a uniform temperature of $230 \pm 9^{\circ}F$ ($110 \pm 5^{\circ}C$) throughout the drying chamber. —Thermostatically controlled oven, capable of maintaining a uniform temperature of $230 \pm 9^{\circ}F$ ($110 \pm 5^{\circ}C$) throughout the drying chamber. These requirements typically require the use of a forced-draft type oven. Preferably the oven should be vented outside the building.
- 6.6 Straightedge—A stiff metal straightedge of any convenient length but not less than $\frac{10-\text{in.}}{254-\text{mm}}$. $\frac{10 \text{ in.}}{250 \text{ mm}}$. The total length of the straightedge shall be machined straight to a tolerance of ± 0.005 = in. (± 0.1 = mm). The scraping edge shall be

beveled if it is thicker than ½-in. (3-mm). in. (3 mm).

- 6.7 Sieves—¾4 -in. (19.0-mm), ¾-in. (9.5-mm), and No. 4 (4.75-mm), conforming to the requirements of Specification E 11E Hin. (19.0 mm), ¾ in. (9.5 mm), and No. 4 (4.75 mm), conforming to the requirements of Specification E 11E11.
- 6.8 Mixing Tools—Miscellaneous tools such as mixing pan, spoon, trowel, spatula, etc., or a suitable mechanical device for thoroughly mixing the sample of soil with increments of water. —Miscellaneous tools such as mixing pan, spoon, trowel, spatula, spraying device (to add water evenly), and (preferably, but optional) suitable mechanical device for thoroughly mixing the subspecimen of soil with increments of water.

7. Standardization/Calibration

- 7.1 Perform <u>ealibrations</u> standardizations before initial use, after repairs or other occurrences that might affect the test results, at intervals not exceeding 1,000 test specimens, or annually, whichever occurs first, for the following apparatus:
 - 7.1.1 Balance—Evaluate in accordance with Specification D 4753D4753.
 - 7.1.2 *Molds*—Determine the volume as described in Annex A1.
- 7.1.3 *Manual Rammer*—Verify the free fall distance, rammer mass, weight, and rammer face <u>are in accordance</u> with 6.2. Verify the guide sleeve requirements <u>are in accordance</u> with 6.2.1.
- 7.1.4 *Mechanical Rammer*—Calibrate—Verify and adjust <u>if necessary that</u> the mechanical rammer <u>is in accordance with Test Methods Method</u> D 2168D2168. In addition, the clearance between the rammer and the inside surface of the mold shall be verified in accordance with 6.2.2.

8. Test Sample

8.1The required sample mass for Procedures A and B is approximately 35-lbm (16-kg), and for Procedure C is approximately 65-lbm (29-kg) of dry soil. Therefore, the field sample should have a moist mass of at least 50-lbm (23-kg) and 100-lbm (45-kg), respectively.

8.2Determine the percentage of material retained on the No. 4 (4.75-mm), 3/8Test Specimen

- 8.1 The minimum specimen (test fraction) mass for Methods A and B is about 16 kg, and for Method C is about 29 kg of dry soil. Therefore, the field sample should have a moist mass of at least 23 kg and 45 kg, respectively. Greater masses would be required if the oversize fraction is large (see 10.2 or 10.3) or an additional molding water content is taken during compaction of each point (see 10.4.2.1).
- 8.2 If gradation data is not available, estimate the percentage of material (by mass) retained on the No. 4 (4.75-mm), ³/₈-in. (9.5-mm), or ³/₄-in. (19.0-mm) sieve as appropriate for choosing Procedure A, B, or C. Make this determination by separating out a representative portion from the total sample and determining the percentages passing the sieves of interest by Test Methods D 422D 422 or Method C 136C 136. It is only necessary to calculate percentages for the sieve or sieves for which information is desired.-in. (19.0-mm) sieve as appropriate for selecting Method A, B, or C, respectively. If it appears the percentage retained of interest is close to the allowable value for a given Method (A, B, or C), then either:
 - 8.2.1 Select a Method that allows a higher percentage retained (B or C). 63-650b-667664ed8fa/astm-d698-0
- 8.2.2 Using the Method of interest, process the specimen in accordance with 10.2 or 10.3, this determines the percentage retained for that method. If acceptable, proceed, if not go to the next Method (B or C).
- 8.2.3 Determine percentage retained values by using a representative portion from the total sample, and performing a simplified or complete gradation analysis using the sieve(s) of interest and Test Method D 6913 D6913or C 136C136. It is only necessary to calculate the retained percentage(s) for the sieve or sieves for which information is desired.

9. Preparation of Apparatus

9.1Select the proper compaction mold in accordance with the procedure (A, B, or C) being used. Determine and record its mass to the nearest gram. Assemble the mold, base and extension collar. Check the alignment of the inner wall of the mold and mold extension collar. Adjust if necessary.

9.2Check that the rammer assembly is in good working condition and that parts are not loose or worn. Make any necessary adjustments or repairs. If adjustments or repairs are made, the rammer must be recalibrated.

9.1 Select the proper compaction mold(s), collar, and base plate in accordance with the Method (A, B, or C) being used. Check that its volume is known and determined with or without base plate, free of nicks or dents, and will fit together properly.

Note 7-Mass requirements are given in 10.4.

9.2 Check that the manual or mechanical rammer assembly is in good working condition and that parts are not loose or worn. Make any necessary adjustments or repairs. If adjustments or repairs are made, the rammer must be re-standardized.

10. Procedure

- 10.1 *Soils*:
- 10.1.1Do not reuse soil that has been previously laboratory compacted.
- 10.1.2When using this test method for soils containing hydrated halloysite, or where past experience with a particular soil indicates that results will be altered by air drying, use the moist preparation method (see

- 10.1.1 Do not reuse soil that has been previously compacted in the laboratory. The reuse of previously compacted soil yields a significantly greater maximum dry unit weight (1, p. 31).
- 10.1.2 When using this test method for soils containing hydrated halloysite, or in which past experience indicates that results will be altered by air-drying, use the moist preparation method (see 10.2).
- 10.1.3Prepare the soil specimens for testing in accordance with). In referee testing, each laboratory has to use the same method of preparation, either moist (preferred) or air-dried.
 - 10.1.3 Prepare the soil specimens for testing in accordance with 10.2 (preferred) or with 10.3.
- 10.2 Moist Preparation Method (preferred)—Without previously drying the sample/specimen, parocess it throughover a No. 4 (4.75-mm), 3%-in. (9.5-mm), or 3/4-in. (19.0-mm) sieve, depending on the procedure (A, B, or C) being used. Determine the water content of the processed soil.
- 10.2.1Prepare at least four (preferably five) specimens having water contents such that they bracket the estimated optimum water content. A specimen having a water content close to optimum should be prepared first by trial additions of water and mixing (see Note 7). Select water contents for the rest of the specimens to provide at least two specimens wet and two specimens dry of optimum, and water contents varying by about 2%. At least two water contents are necessary on the wet and dry side of optimum to accurately define the dry unit weight compaction curve (see-in. (19.0-mm) sieve, depending on the Method (A, B, or C) being used or required as covered in 8.2. For additional processing details, see Test Method D 6913D6913. Determine and record the mass of both the retained and passing portions (oversize fraction and test fraction, respectively) to the nearest g. Oven dry the oversize fraction and determine and record its dry mass to the nearest g. If it appears more than 0.5 % of the total dry mass of the specimen is adhering to the oversize fraction, wash that fraction. Then determine and record its oven dry mass to the nearest g. Determine and record the water content of the processed soil (test fraction). Using that water content, determine and record the oven dry mass of the test fraction to the nearest g. Based on these oven dry masses, the percent oversize fraction, P_C , and test fraction, P_C , shall be determined and recorded, unless a gradation analysis has already been performed, see Section 11 on Calculations.
- 10.2.1 From the test fraction, select and prepare at least four (preferably five) subspecimens having molding water contents such that they bracket the estimated optimum water content. A subspecimen having a molding water content close to optimum should be prepared first by trial additions or removals of water and mixing (see Note 8). Select molding water contents for the rest of the subspecimens to provide at least two subspecimens wet and two subspecimens dry of optimum, and molding water contents varying by about 2 %. At least two molding water contents are necessary on the wet and dry side of optimum to define the dry-unit-weight compaction curve (see 10.5). Some soils with very high optimum water content or a relatively flat compaction curve may require larger molding water content increments to obtain a well-defined maximum dry unit weight. Water-Molding water content increments should not exceed about 4 %.

Note7—With practice it is usually possible to visually judge a point near optimum water content. Typically, soil at optimum water content can be squeezed into a lump that sticks together when hand pressure is released, but will break cleanly into two sections when "bent". At water contents dry of optimum soils tend to crumble; wet of optimum soils tend to stick together in a sticky cohesive mass. Optimum water content is typically slightly less than the plastic limit.

10.2.2Use approximately 5-lbm (2.3-kg) of the sieved soil for each specimen to be compacted using Procedure A or B, or 13-lbm (5.9-kg) using Procedure C. To obtain the specimen water contents selected in 8—With practice it is usually possible to visually judge a point near optimum water content. Typically, cohesive soils at the optimum water content can be squeezed into a lump that sticks together when hand pressure is released, but will break cleanly into two sections when "bent." They tend to crumble at molding water contents dry of optimum; while, they tend to stick together in a sticky cohesive mass wet of optimum. The optimum water content is typically slightly less than the plastic limit. While for cohesionless soils, the optimum water content is typically close to zero or at the point where bleeding occurs.

10.2.2 Thoroughly mix the test fraction, then using a scoop select representative soil for each subspecimen (compaction point). Select about 2.3 kg when using Method A or B, or about 5.9 kg for Method C. Test Method D 6913D6913 section on Specimen and Annex A2 gives additional details on obtaining representative soil using this procedure and why it is the preferred method. To obtain the subspecimen's molding water contents selected in 10.2.1, add or remove the required amounts of water as follows: to add water, spray it into the soil during mixing; to remove water, allow the soil to dry in air at ambient temperature or in a drying apparatus such that the temperature of the sample does not exceed 140°F (60°C). Mix the soil frequently during drying to maintain an even water content distribution. Thoroughly mix each specimen to ensure even distribution of water throughout and then place in a separate covered container and allow to stand in accordance with Table 1 prior to compaction. For the purpose of selecting a standing time, the soil may be classified using Test Method D 2487D 2487, Practice D 2488D 2488 or data on other samples from the same material source. For referee testing, classification shall be by Test Method D 2487D 2487. add or remove the required amounts of water as follows. <u>10.3</u> *Dry Preparation Method*—If the sample/specimen is too damp to be friable, reduce the water content by air drying until the material is friable. Drying may be in air or by the use of drying apparatus such that the temperature of the sample does not exceed 140°F (60°C). Thoroughly break up the aggregations in such a manner as to avoid breaking individual particles. <u>PassProcess</u> the material <u>throughover</u> the appropriate sieve: No. 4 (4.75-mm), 3/8-in. (9.5-mm), or 3/4-in. (19.0-mm). When preparing the material by passing over the 3/4-in. sieve for compaction in the 6-in. mold, break up aggregations sufficiently to at least pass the 3/8-in. sieve in order to facilitate the distribution of water throughout the soil in later mixing.

10.3.1Prepare at least four (preferably five) specimens in accordance with 10.2.1-in. sieve in order to facilitate the distribution of water throughout the soil in later mixing. Determine and record the water content of the test fraction and all masses covered in 10.2, as applicable to determine the percent oversize fraction, P_C , and test fraction, P_C .

10.3.2Use approximately 5-lbm (2.3-kg) of the sieved soil for each specimen to be compacted using Procedure A or B, or 13-lbm (5.9-kg) using Procedure C. Add the required amounts of water to bring the water contents of the specimens to the values selected in 10.3.1. Follow the specimen preparation procedure specified in

10.3.1 From the test fraction, select and prepare at least four (preferably five) subspecimens in accordance with 10.2.1 and 10.2.2for drying the soil or adding water into the soil and curing each test specimen.

10.4, except for the following: Use either a mechanical splitting or quartering process to obtain the subspecimens. As stated in Test Method D 6913D6913, both of these processes will yield non-uniform subspecimens compared to the moist procedure. Typically, only the addition of water to each subspecimen will be required.

- 10.4 Compaction—After curing, if required, each specimen shall be compacted as follows:
- 10.4.1Determine and record the mass of the mold or mold and base plate.

10.4.2Assemble and secure the mold and collar to the base plate. The mold shall rest on a uniform rigid foundation, such as provided by a cylinder or cube of concrete with a mass of not less than 200-lbm (91-kg). Secure the base plate to the rigid foundation. The method of attachment to the rigid foundation shall allow easy removal of the assembled mold, collar and base plate after compaction is completed.

10.4.3Compact the specimen in three layers. After compaction, each layer should be approximately equal in thickness. Prior to compaction, place the loose soil into the mold and spread into a layer of uniform thickness. Lightly tamp the soil prior to compaction until it is not in a fluffy or loose state, using either the manual compaction rammer or a 2-in. (5-mm) diameter cylinder. Following compaction of each of the first two layers, any soil adjacent to the mold walls that has not been compacted or extends above the compacted surface shall be trimmed. The trimmed soil may be included with the additional soil for the next layer. A knife or other suitable device may be used. The total amount of soil used shall be such that the third compacted layer slighly extends into the collar, but does not exceed 1/4-in. (6-mm) above the top of the mold. If the third layer does extend above the top of the mold by more than 1/4-in. (6-mm), the specimen shall be discarded. The specimen shall be discarded when the last blow on the rammer for the third layer results in the bottom of the rammer extending below the top of the compaction mold.

10.4.4Compact each layer with 25 blows for the 4-in. (101.6-mm) mold or with 56 blows for the 6-in. (152.4-mm) mold.

Note8—When compacting specimens wetter than optimum water content, uneven compacted surfaces can occur and operator judgement is required as to the average height of the specimen.

10.4.5In operating the manual rammer, take care to avoid lifting the guide sleeve during the rammer upstroke. Hold the guide sleeve steady and within 5° of vertical. Apply the blows at a uniform rate of approximately 25 blows/min and in such a manner as to provide complete, uniform coverage of the specimen surface.

10.4.6Following compaction of the last layer, remove the collar and base plate from the mold, except as noted in <u>—After</u> standing (curing), if required, each subspecimen (compaction point) shall be compacted as follows:

10.4.1 Determine and record the mass of the mold or mold and base plate, see 10.4.7. A knife may be used to trim the soil adjacent to the collar to loosen the soil from the collar before removal to avoid disrupting the soil below the top of the mold.

10.4.7Carefully trim the compacted specimen even with the top of the mold by means of the straightedge scraped across the top of the mold to form a plane surface even with the top of the mold. Initial trimming of the specimen above the top of the mold with a knife may prevent the soil from tearing below the top of the mold. Fill any holes in the top surface with unused or trimmed soil from the specimen, press in with the fingers, and again scrape the straightedge across the top of the mold. Repeat the appropriate preceding operations on the bottom of the specimen when the mold volume was determined without the base plate. For very wet or dry soils, soil or water may be lost if the base plate is removed. For these situations, leave the base plate attached to the mold. When the base plate is left attached, the volume of the mold must be calibrated with the base plate attached to the mold rather than a plastic or glass plate as noted in Annex A1, A1.4.

10.4.8Determine and record the mass of the specimen and mold to the nearest gram. When the base plate is left attached, determine and record the mass of the specimen, mold and base plate to the nearest gram.

10.4.9Remove the material from the mold. Obtain a specimen for water content by using either the whole specimen (preferred method) or a representative portion. When the entire specimen is used, break it up to facilitate drying. Otherwise, obtain a portion by slicing the compacted specimen axially through the center and removing about 500-g of material from the cut faces. Obtain the water content in accordance with Test Method D 2216D 2216

10.4.2 Assemble and secure the mold and collar to the base plate. Check the alignment of the inner wall of the mold and mold extension collar. Adjust if necessary. The mold shall rest, without wobbling/rocking on a uniform rigid foundation, such as provided by a cylinder or cube of concrete with a weight or mass of not less than 200-lbf or 91-kg, respectively. Secure the base plate to the rigid foundation. The method of attachment to the rigid foundation shall allow easy removal of the assembled mold, collar and base plate after compaction is completed.

10.4.2.1 During compaction, it is advantageous but not required to determine the water content of each subspecimen. This provides a check on the molding water content determined for each compaction point and the magnitude of bleeding, see 10.4.9. However, more soil will have to be selected for each subspecimen than stated in 10.2.2.

10.5Following compaction of the last specimen, compare the wet unit weights to ensure that a desired pattern of obtaining data on each side of the optimum water content will be attained for the dry unit weight compaction curve. Plotting the wet unit weight and water content of each compacted specimen can be an aid in making the above evaluation. If the desired pattern is not obtained, additional compacted specimens will be required. Generally, one water content value wet of the water content defining the maximum wet unit weight is sufficient to ensure data on the wet side of optimum water content for the maximum dry unit weight.

11.Calculation

11.1Calculate the dry unit weight and water content of each compacted specimen as explained in 11.3 and 11.4. Plot the values and draw the compaction curve as a smooth curve through the points (see example,

10.4.3 Compact the soil in three layers. After compaction, each layer should be approximately equal in thickness and extend into the collar. Prior to compaction, place the loose soil into the mold and spread into a layer of uniform thickness. Lightly tamp the soil prior to compaction until it is not in a fluffy or loose state, using either the manual rammer or a 2±-in. (50±-mm) diameter cylinder. Following compaction of each of the first two layers, any soil that has not been compacted; such as adjacent to the mold walls or extends above the compacted surface (up the mold walls) shall be trimmed. The trimmed soil shall be discarded. A knife or other suitable device may be used. The total amount of soil used shall be such that the third compacted layer slightly extends into the collar, but does not extend more than approximately ½-in. (6-mm) above the top of the mold. If the third layer does extend above this limit, then the compaction point shall be discarded. In addition, the compaction point shall be discarded when the last blow on the rammer for the third layer results in the bottom of the rammer extending below the top of the compaction mold; unless the soil is pliable enough, that this surface can easily be forced above the top of the compaction mold during trimming (see Note 9).

10.4.4 Compact each layer with 25 blows for the 4-in. (101.6-mm) mold or with 56 blows for the 6-in. (152.4-mm) mold. The manual rammer shall be used for referee testing.

10.4.5 In operating the manual rammer, take care to avoid lifting the guide sleeve during the rammer upstroke. Hold the guide sleeve steady and within 5° of vertical. Apply the blows at a uniform rate of about 25 blows/min and in such a manner as to provide complete, uniform coverage of the specimen surface. When using a 4-in. (101.6-mm) mold and manual rammer, follow the blow pattern given in Fig. 3). Plot dry unit weight to the nearest 0.1 lbf/ft³ (0.2 kN/m³) and water content to the nearest 0.1%. From the compaction curve, determine the optimum water content and maximum dry unit weight. If more than 5% by weight of oversize material was removed from the sample, calculate the corrected optimum water content and maximum dry unit weight of the total
