

Designation: D441 – 07

## Standard Test Method of Tumbler Test for Coal<sup>1</sup>

This standard is issued under the fixed designation D441; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon ( $\epsilon$ ) indicates an editorial change since the last revision or reapproval.

### 1. Scope

1.1 This test method covers the determination of the relative friability of a particular size of sized coal. It affords a means of measuring the liability of coal to break into smaller pieces when subjected to repeated handling at the mine or subsequently, by the distributor or by the consumer. This test method is serviceable for ascertaining the similarity of coals in respect to friability rather than for determining values within narrow limits to emphasize their dissimilarity. This test method also may serve to indicate the relative extent to which sized coals will suffer size degradation in certain mechanical feed devices. This test method may be used for differentiating between certain ranks and grades of coal, and therefore the test method is of service for coal classification purposes.

1.2 The values stated in inch-pound units shall be regarded as the standard. Mass may be expressed in metric values.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

### 3. Significance and Use

3.1 This test method is a measure of the resistance of the coal to breakage upon impact and abrasion as the coal rubs together and against the walls of the transportation vehicle.

### 4. Apparatus

4.1 *Porcelain Jar Tumbler*, consisting of a cylindrical porcelain jar of uniform dimensions, 7¼ in. (184 mm) in diameter and 7¼ in. in depth, inside measurements, such as is used for pulverizing coal samples for analysis. The jar shall be fitted inside an iron frame with lifting shelves constructed as shown in Fig. 1. The two rings, *a*, shall be 7⅞ in. (181 mm) in outside diameter and shall be made of ¾- by ⅛-in. (19- by 3-mm) iron. The three ledges or shelves, *b*, 6½ by ¾ by ⅛ in. (165 by 19 by 3 mm), shall be attached radially to the rings by means of small brackets, *c*, the ends of the shelves being flush with the outer edges of the rings. The shelves shall be attached so that there will be ⅝-in. (15.9-mm) clearance between their outer edge and the outside of the ring. Rivets, not bolts, shall be used in constructing the frame. As the jars available commercially are not of absolutely uniform size, the measurements of the frame may be slightly varied to suit individual cases. The frame shall be fixed inside the jar by means of wedges between the rings and the inside wall of the jar so that its axis shall coincide as nearly as possible with the axis of the jar, and so that the frame will rotate with the jar. The jar shall be closed by a set-in porcelain lid resting upon a heavy rubber gasket and sealed tightly according to the customary procedure with such jars, that is, by means of a bolt working against the lid. The bolt shall be set in a crossbar, the ends of which shall be held by a metal strip which fits around the body of the jar. For tumbling, the jar shall be laid in a horizontal position in a suitable support or rack and rotated about its cylindrical axis at the rate of 40 rpm. The assembled apparatus is illustrated in Fig. 2.

4.2 *Optional Iron Jar Tumbler*—An iron jar may be substituted for the porcelain jar specified in 4.1, provided it has approximately the same internal dimensions, namely, 7¼ in. in diameter by 7¼ in. in depth. A jar constructed of cast iron is recommended, and the interior machined to the required internal dimensions. For making it sufficiently light for lifting,

Metric Equivalents					
in.	1/8	5/8	3/4	6 1/2	7 1/8
(mm)	(3.18)	(15.9)	(19.0)	(165)	(181)

FIG. 1 Steel Frame Used in Jar Mill

4.3 *Sieves*—For sizing the sample for test, square-hole sieves having 1.50- and 1.06-in. (38.1- and 26.9-mm) actual openings between the wires shall be used. These sieves may be fitted into frames, 12 by 30 in. (305 by 762 mm) or larger. For sieving the coal after tumbling, square-hole sieves having 1.06-, 0.750-, 0.530-, 0.375-, 0.0469-, and 0.0117-in. (26.9-, 19.0-, 13.5-, 9.51-, 1.19-, and 0.297-mm) actual openings between the wires shall be used. For this purpose, round, metal-framed sieves 8 in. (200 mm) in diameter are suitable. The sieves shall conform to Specification E11.

4.4 *Balance*—The balance used for weighing the sample shall be sensitive to 1 g.

### 5. Sampling

5.1 *Collection of Gross Sample*—Collect the gross sample of coal in accordance with Practice D2234/D2234M and Test Method D4749.

#### 5.2 Preparation of Sample:

5.2.1 Make a preliminary sieving of a representative portion, approximately 100 lbs (45 kg), of the gross sample, using square-hole sieves with 1.06- and 1.50-in. (26.9- and 38.1-mm) openings. If this preliminary sieving indicates that the pieces of coal are mostly smaller than 1.50 in., sieve successive representative portions of the gross sample until at least 25 lbs (11 kg) of the 1.06- to 1.50-in. size are obtained. If most of the pieces obtained by the preliminary sieving are larger than 1.50 in., conduct sieving of representative portions of the gross sample until at least 50 lbs (23 kg) of the sieved material remaining on the 1.06-in. sieve are available. Then break the pieces so obtained that are larger than 1.50 in. with a hammer until they pass the 1.50-in. sieve, avoiding as much as possible the production of pieces smaller than 1.06 in. Should the combined weights of the 1.06- to 1.50-in. size, obtained by sieving before and after hammer breakage of the larger pieces, be less than the required 25 lbs, augment the amount by further sieving and breakage of additional representative portions, or the remainder of the gross sample, taking care to discard all pieces in which noticeable cracks have developed by hammer breakage. Take care also to provide pieces covering the whole range of the 1.06- to 1.50-in. size in both the 25-lbs composite sample, and in each 1000-g sample taken for test as in Section 5. This may be accomplished by the use of a 1.25-in. (31.5-mm) sieve to see that approximately half of the weight of the pieces comprising these samples will be between 1.06 and 1.25 in. and half between 1.25 and 1.50 in.

5.2.2 Mix thoroughly the total quantity of the 1.06- to 1.50-in. size and then resieve it to pass the 1.50-in. sieve and be retained on the 1.06-in. sieve. Place only a thin layer of coal on the sieve so as to allow the pieces to be in direct contact with the sieve openings. Upend by hand individual pieces of coal not passing readily through the sieve to determine whether in any position they pass the sieve.

### 6. Procedure

6.1 Weigh approximately 1000 g of the coal sample, prepared in accordance with 5.1, and place it in the jar. Rotate the jar for 1 h in the tumbler test machine at  $40 \pm 1$  rpm. To standardize the time of tumbling, use a revolution counter,

NOTE 1—On the bench are shown typical jar mills in which the three-vane iron frames are fitted, together with a set of 8-in. (200 mm) diameter sieves and a 1000-g charge of 1.06- to 1.50-in. (26.5 to 38.1-mm) size coal. The jar to the left is one of the regular porcelain jars, and that to the right an optional iron jar.

FIG. 2 Tumbler Test Apparatus

the jar may have a wall thickness of not less than 1/4 in. (6.35 mm), except at each end. It is recommended that the lid, rubber gasket, and the metal strip that passes from the bottom up the outside of the jar to serve in holding in place the crossbar above the lid, be similar in design with those for the porcelain jar. The wall of the iron jar for a distance of approximately 1 in. (25.4 mm) from the top shall have a thickness of at least 1/2 in. (12.7 mm) to correspond with that of the porcelain jar; and in order that the metal strip may fit evenly, the lower inch of the wall should also have a thickness of not less than 1/2 in.
