

Designation: ~~D6521-05~~ Designation: D 6521 - 08

## Standard Practice for Accelerated Aging of Asphalt Binder Using a Pressurized Aging Vessel (PAV)<sup>1</sup>

This standard is issued under the fixed designation D 6521; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon ( $\epsilon$ ) indicates an editorial change since the last revision or reapproval.

### 1. Scope

1.1 This practice covers the accelerated aging (oxidation) of asphalt binders by means of pressurized air and elevated temperature. This is intended to simulate the ~~type of changes~~ changes in rheology which occur in asphalt binders during in-service oxidative aging but may not accurately simulate the relative rates of aging. It is normally intended for use with residue from Test Method D 2872 (RTFOT), which is designed to simulate plant aging.

NOTE 1—Modified asphalt binders may phase separate or form skins during oven conditioning in Test Method D 2872 (RTFOT); the results from subsequent testing of this residue may not be representative of modified asphalts short-term aged under field conditions. Phase separation, or formation of skins, or both can also occur during PAV aging-conditioning. Therefore, the practice may not be suitable for some modified asphalts.

NOTE 2—PAV conditioning has not been validated for materials containing particulate materials.

1.2 The aging of asphalt binders during service is affected by ambient temperature ~~and air pressure~~ and by mixture-associated variables, such as the volumetric proportions of the mix, the permeability of the mix, properties of the aggregates, and possibly other factors. This conditioning process is intended to provide an evaluation of the relative resistance of different asphalt binders to oxidative aging at selected elevated aging temperatures and pressures, but cannot account for mixture variables or provide the relative resistance to aging at in-service conditions.

1.3 The values stated in SI units are to be regarded as the standard. Values in parentheses in inch-pound units are provided for informational purposes only.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

### 3. Terminology

#### 3.1 Definitions:

3.1.1 Definitions of terms used in this practice may be found in Terminology D 8, determined from common English usage, or combinations of both.

### 4. Summary of Practice

4.1 Asphalt binder is normally first aged/conditioned using Test Method D 2872 (RTFOT). ~~A specified thickness of residue~~ Residue from the RTFOT is then placed in standard ~~TFOT~~-stainless steel pans and aged at the specified ~~aging/conditioning~~ temperature for 20 h in a vessel pressurized with air to 2.10 MPa. ~~Aging~~—The conditioning temperature is selected according to the grade of this asphalt binder. The residue is then vacuum degassed.

### 5. Significance and Use

5.1 This practice is designed to simulate the ~~type of~~ in-service oxidative aging that occurs in asphalt binders during pavement service. Residue from this conditioning practice may be used to estimate the physical or chemical properties of asphalt binders after several years of in-service aging in the field.

5.2 Binders ~~aged/conditioned~~ using this practice are normally used to determine specification properties in accordance with Specification D 6373, ~~or AASHTO M 320, or AASHTO MP 1a.~~

5.3 For asphalt binders of different grades or from different sources, there is no unique correlation between the ~~aging~~ time and temperature in this conditioning practice and in-service pavement age and temperature. Therefore, for a given set of in-service climatic conditions, it is not possible to select a single PAV ~~aging time and elevated conditioning time,~~ temperature and pressure that will predict the properties or the relative rankings of the properties of ~~all~~ asphalt binders after a specific set of in-service exposure conditions.

5.4 The relative degree of hardening of different asphalt binders varies with ~~aging/conditioning~~ temperatures and pressures in the PAV. Therefore, two asphalt binders may age at a similar rate at one condition of temperature and pressure, but age differently at another condition. Hence, the relative rates of aging for a set of asphalts at PAV conditions may differ significantly from the actual in-service relative rates at lower ~~pavement~~ temperatures and ~~ambient~~ pressures.

### 6. Apparatus

6.1 An equipment system consisting of a pressure vessel, ovens, pressure-controlling devices, temperature-controlling devices, pressure and temperature measuring devices, and a temperature and pressure recording system (see Fig. 1).

6.1.1 *Pressure Vessel*—A stainless steel pressure vessel designed to operate at  $2.1 \pm 0.1$  MPa between 90 and 110°C with interior dimensions adequate to hold ten ~~TFOT~~PAV pans and a pan holder. The ~~pressure vessel~~pan holder shall contain a pan holder ~~be~~ capable of holding ten ~~TFOT~~PAV stainless steel pans in a horizontal (level) position, such that the asphalt binder film thickness is reasonably uniform. The holder shall be designed for easy insertion and removal from the vessel when the holder, pans, and asphalt binder are at the ~~aging/conditioning~~ temperature. A schematic showing a possible configuration of the vessel, pan holder and pans, and specifying dimensional requirements is shown in Fig. 2.

NOTE 3—The vessel may be a separate unit to be placed in a forced draft oven for conditioning the asphalt binders or an integral part of the temperature control system (for example, by direct heating of the vessel or by surrounding the vessel with a permanently affixed heating unit, forced air oven, or liquid bath). For practical purposes, it is recommended that the vessel have the dimensions of 250 mm in diameter and 265 mm in height. ~~Research has shown that the volume of the vessel is not an important factor in hardening due to aging.~~

#### 6.1.2 Pressure and Temperature Controlling Devices:

6.1.2.1 A pressure relief valve that prevents pressure in the vessel from exceeding the design pressure of the vessel, but in no case exceeding 2.5 MPa during the ~~aging/conditioning~~ procedure.

6.1.2.2 A pressure regulator or regulating system capable of controlling the pressure within the vessel to  $\pm 0.02$  MPa, and with a capacity adequate to reduce the pressure from the source of compressed air, so that the pressure within the loaded pressure vessel is maintained at  $2.1 \pm 0.1$  MPa gauge (relative) pressure during the ~~aging/conditioning~~ process.

6.1.2.3 A slow-release bleed valve ~~or pressure controller~~ that allows the pressure in the vessel at the completion of the conditioning procedure to be reduced from 2.1 MPa to local atmospheric pressure within 8 to 15 min.

6.1.3 *Temperature Controlling Device* —A digital temperature control device as described in 6.1.4.1 or 6.1.4.2 for maintaining the temperature during the ~~aging/conditioning~~ procedure within the pressure vessel at the ~~aging/conditioning~~ temperature  $\pm 0.5^\circ\text{C}$ .

6.1.3.1 A heating device (forced-draft oven or fluid bath) capable of restoring the ~~aging/conditioning~~ temperature within the vessel after loading the pans and the pan holder and prior to pressurizing the vessel within 2 h of placing the loaded vessel in the heating device. ~~Maintain~~—The device shall be capable of maintaining the temperature within the pressure vessel at the ~~aging/conditioning~~ temperature  $\pm 0.5^\circ\text{C}$ . If an oven is used, the oven shall have sufficiently large interior dimensions to allow forced air to freely circulate within the oven and around the pressure vessel when the vessel is placed in the oven. The oven shall contain a stand or shelf that supports the loaded pressure vessel in a level position above the lower surface of the oven.

6.1.3.2 A pressure vessel with an integral temperature control system that is capable of restoring the ~~pre-aging~~pre-conditioning temperature, as determined in 9.3, within the vessel after loading the pans and the pan holder, prior to pressurizing the vessel within

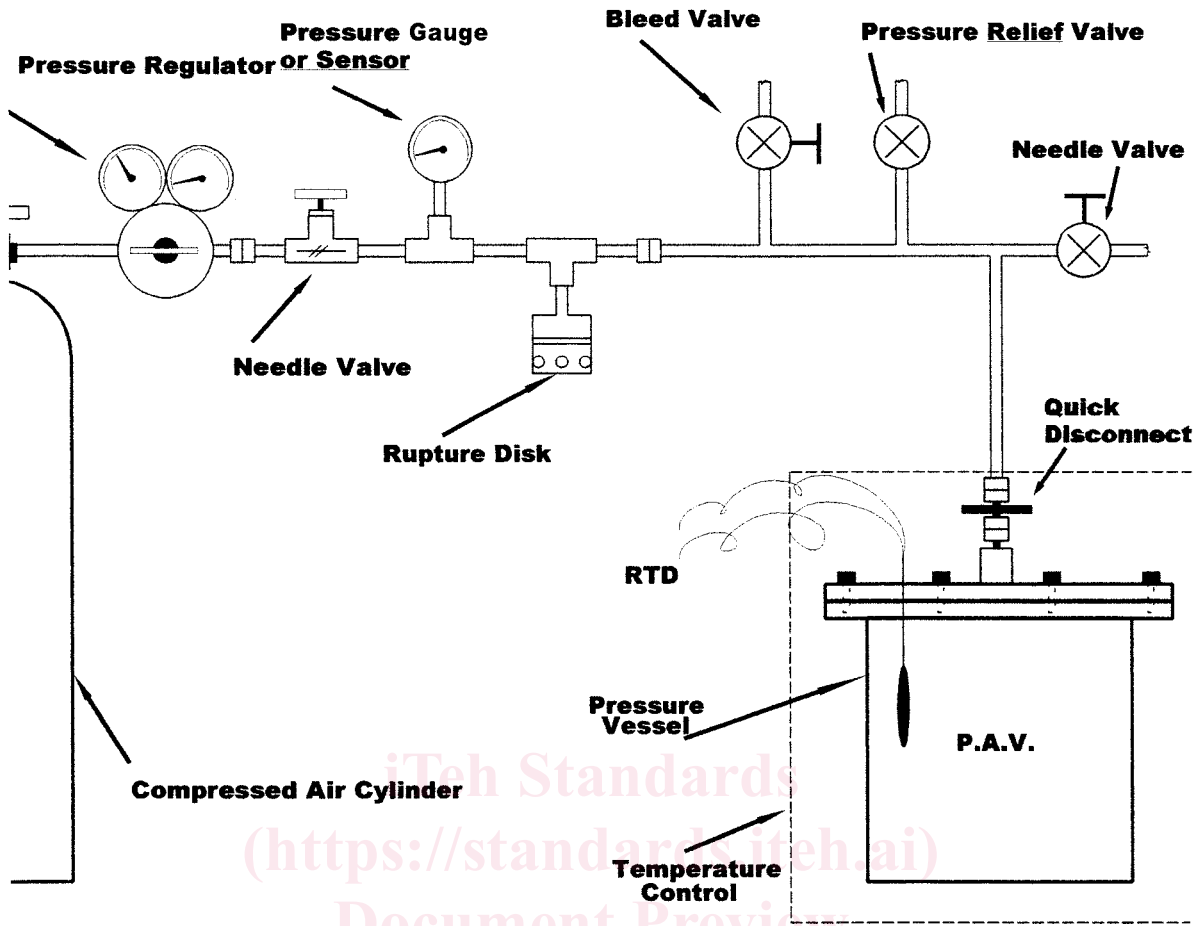

FIG. 1 Schematic of PAV Test System

NOTE 1—Distance “a” controls the levelness of the pan. The assembly shall be supported at three or more support points. The distance “a”, measured from each assembly support point to the bottom of the pan (top of shelf or pan support point), shall be controlled to  $\pm 0.05$  mm.

NOTE 2—Distances  $b_1$  and  $b_2$  shall be such that any active portion of the temperature transducer is  $\geq 10$  mm from any adjacent surface.

NOTE 3—Distance “c” shall be  $\geq 12$  mm.

FIG. 2 Schematic Showing Location of Pans and RTD Within PAV
