Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2. www.iso.org/directives

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received. www.iso.org/patents

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

The committee responsible for this document is ISO/TC 126, *Tobacco and tobacco products*.

This second edition cancels and replaces the first edition (ISO 20774:2007) which has been editorially revised.

iTeh STANDARD PREVIEW
(standards.iteh.ai)
<https://standards.iteh.ai/catalog/standards/sist/d0fb156b-59dd-4f12-8b81-7b54df419f56/iso-20774-2013>

Introduction

Cigarettes are manufactured to close tolerances using strict quality control procedures.

However, the main constituents involved in the manufacture are derived from natural products (such as tobacco and paper) and this results in a final product which is intrinsically variable. Further complexity arises as the cigarette is combusted during smoking to yield the cigarette smoke.

The quantitative measurement of carbon monoxide is therefore dependent on the arbitrary definition of the means used to generate and collect the smoke. In particular, the ambient conditions (e.g. temperature, humidity, air movement within the laboratory) under which the test pieces are conditioned and smoke is collected play a critical role in the accuracy of the measurement.

Sidestream smoke in this International Standard is understood to be the smoke that is evolved from the cigarette during the smoking run other than from the mouth end (which is called mainstream smoke).

NOTE Side stream smoke is distinguished from environmental tobacco smoke (ETS), which is a mixture of aged and diluted exhaled mainstream smoke and aged and diluted sidestream smoke, and for the assessment of which the present method does not apply.

From the time that scientists have attempted to determine carbon monoxide yields in sidestream smoke, many different methods have been adopted. However, experience has shown some procedures to be more reliable and more amenable to handling of large numbers of samples. With these factors in mind, during the 1999–2002 period, collaborative studies by a task force composed of CORESTA (www.coresta.org) members have shown that improvements in repeatability and reproducibility result when some restrictions are placed upon the wide variety of methods and practices described in existing methods.

This International Standard, produced after much collaborative experimentation by many laboratories in many countries, reflects the results of the optimization proposed and validated by the task force and provides one set of procedures that are the accepted reference procedures and for which repeatability and reproducibility of the determinations were assessed. Experience in the task force has shown how strict adherence to the detailed set up and conditions of the method, as well as the degree of proficiency of the operator, affect the precision of the results.

Further, it is preferable that the selected method be compatible with different modes of cigarette equilibration or puffing parameters for the smoking of the tested pieces. The standards defined by ISO for the determination of mainstream smoke yields were, however, followed to the largest possible extent, although the machines used by the different laboratories were all of a linear type.

This method is a machine method and it allows cigarettes to be smoked using a strictly controlled set of parameters. Thus it enables the sidestream smoke carbon monoxide yields from cigarettes, when smoked by this procedure, to be compared and ranked. In the course of its studies, the task force demonstrated the value of comparing the analytical processes and their stability by use of the CORESTA monitor test piece for determining sidestream smoke CO yields.

Since the determination of sidestream smoke CO yield is by nature more complex and delicate than its counterpart performed on mainstream smoke, it is highly recommended to include a monitor test piece in the smoking plans, as is done in mainstream smoke determinations. It is possible to use the CORESTA monitor or any other internally designed monitor test piece for this purpose. The use of an internationally recognized one is recommended.

ISO 20774:2013

<https://standards.iteh.ai/catalog/standards/sist/d0fb156b-59dd-4f12-8b81-7b54df419f56/iso-20774-2013>

Cigarettes — Determination of carbon monoxide in sidestream smoke — Method using a routine analytical linear smoking machine equipped with a fishtail chimney

WARNING — The use of this International Standard can involve hazardous materials, operations and equipment. This International Standard does not purport to address all the safety problems associated with its use. It is the responsibility of the user of this International Standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

1 Scope

This International Standard is applicable to the determination of carbon monoxide present in the sidestream smoke from cigarettes. The described method is specified using the ISO 3308 smoking parameters (puff volume, duration and frequency) and butt length, but it is technically compatible with other smoking regimes.

NOTE The method may not be directly adaptable to other sidestream smoke analytes. Nevertheless the determination of carbon dioxide was part of the validation study of ISO 20774 carried out by CORESTA. According to the number of reporting laboratories no rigorous statistical analysis of sidestream carbon dioxide data was carried out. Therefore only indicative information about conditions for the determination of CO₂ is provided.

2 Normative references

The following documents, in whole or in part, are normatively referenced in this document and are indispensable for its application. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

3.1

sidestream smoke vapour phase

portion of the sidestream smoke which passes through a Cambridge filter pad under the conditions specified in the method

3.2

smoking process

use of a smoking machine to smoke cigarettes from lighting to final puff

3.3

smoking run

specific smoking process to produce such sidestream smoke from a sample of cigarettes as is necessary for the determination of the smoke components

3.4

laboratory sample

sample intended for laboratory inspection or testing and which is representative of the gross sample or the sub-period sample

3.5

test sample

cigarettes for test taken at random from the laboratory sample and which are representative of each of the increments making up the laboratory sample

3.6

conditioning sample

cigarettes selected from the test sample for conditioning prior to tests for sidestream smoke CO yield

3.7

test portion

group of cigarettes prepared for a single determination and which is a random sample from the test sample or conditioning sample, as appropriate

3.8

monitor test piece

sample produced for a specific test purpose, validated to fulfil requirements within specified tolerances and intended to be used for laboratory purposes only and labelled to clearly indicate that it is not for human use

Note 1 to entry: A monitor test piece is a sample taken from a batch of cigarettes that show the greatest homogeneity with regard to their physical, chemical and smoke yield characteristics.

4 Principle

- Sampling of the test cigarettes.
- Conditioning of the test cigarettes.
- Smoking of the test cigarettes on a smoking machine in accordance with ISO 3308, with the exception of the specifications on air velocity control, and equipped with a fishtail chimney and a filter pad (glass fibre filter pad) for sidestream smoke collection from each channel.
- Collection of sidestream smoke vapour phase and determination of its CO content.

NOTE The determination of the CO content can be done either by an on-line measurement or by off-line measurement. In the latter method, the vapour phase, or a proportion of it, is first collected in a gas bag.

5 Apparatus

Usual laboratory apparatus and in particular the following items.

5.1 Fishtail chimney¹⁾, manufactured in glass, of design and dimensions shown in [Figure 1](#).

1) Details of where to obtain fishtail chimneys are available from ISO/TC 126.

Figure 1 — Fishtail chimney dimensions

5.2 Routine analytical cigarette-smoking machine, modified to accept fishtail chimneys and complying with the requirements of ISO 3308 with the exception of the specifications on air velocity control. A plate shall be fixed underneath each channel, with a minimum length of 120 mm and a minimum width of 50 mm. This plate is positioned so as to cover the totality of the opening at the fishtail chimney bottom, as shown in [Figure 2](#).

Key

- 1 horizontal plate
- 2 mainstream smoke trap and cigarette holder
- 3 fishtail chimney
- 4 location of calibration flow measurement
- 5 pressure and vacuum tubing
- 6 sidestream smoke trap
- 7 quick connect
- 8 flow meter
- 9 flow regulator
- a To vacuum pump and CO collection/detector.

Figure 2 — Sidestream smoke collection system

5.3 Non-dispersive infrared (NDIR) analyser, selective and calibrated for the measurement of carbon monoxide in vapours and gases.

Analysers are available from several manufacturers and should have a preferred working range of a volume fraction of 0 % to 2 % with a linear output. The analyser should have a precision of 1 % of full scale, a linearity of 1 % of full scale, and a repeatability of 0,2 % of full scale, under conditions of constant temperature and pressure. The signal generated by a volume fraction of 10 % of carbon dioxide should not exceed a volume fraction of 0,05 % as carbon monoxide. Its response to a volume fraction of 2 % of water vapour should not exceed a volume fraction of 0,02 % as carbon monoxide.

5.4 Gas sampling bags, needed only if vapour phase collection is done in bags rather than by a continuous flow system.

When a bag is used as the gas-collecting device, it should be large enough to avoid the final pressure of its contents exceeding the ambient atmospheric pressure. The volume of the bag shall also be no greater than twice the volume of the gas content collected at atmospheric pressure.

Collection bag material shall be suitable for carbon monoxide and also for carbon dioxide if it is intended to determine the latter. Tedlar bags are suitable for CO analysis, but will allow carbon dioxide to gradually leak out upon storage, so that their use would mandate an immediate quantification of the latter. Saran has been shown to be an effective material for the sampling of both gases.

5.5 Vacuum pump or pumps and flow control devices, capable of maintaining an air flow of 3 l/min through each fishtail chimney and collection train.

5.6 PVC tubing, tubing of approximately 8 mm inside diameter, 11 mm outside diameter, to connect the sidestream smoke trap, in-line flow meter, flow regulator, vacuum pump, gas sampling bag (if used) and CO analyser.

5.7 Timer, stopwatch, clock or timing device capable of measuring the elapsed time in seconds.

5.8 Flow monitoring and regulating system on each channel, comprising an in-line continuous-reading flow meter, capable of monitoring the flow with a resolution of 0,2 l/min, followed by a precision flow-regulating device.

5.9 Primary flow meter, capable of accurately measuring a flow-rate of 3 l/min to a precision of 0,1 l/min, to be used in setting the air flow in each fishtail chimney before a smoke run. As this is a primary measurement, the flow meter should measure the time needed to flush a known volume.

5.10 Soap bubble flow meter or alternative displacement flow meter, capable of measuring a displaced volume of at least the desired puff volume, with an accuracy of $\pm 0,2$ ml and a resolution of 0,1 ml.

5.11 Apparatus for the determination of puff duration and frequency.

5.12 Analytical balance, with a resolution of 0,1 mg.

5.13 Draw resistance testing equipment, as specified in ISO 6565.

5.14 Conditioning enclosure, carefully maintained in accordance with the conditions specified in ISO 3402.

5.15 Length-measuring device, suitable for measuring to the nearest 0,5 mm.

5.16 Apparatus for the determination of diameter, in accordance with ISO 2971.

5.17 Barometer, capable of measuring atmospheric pressures to the nearest 0,1 kPa.

6 Reagents

Use only reagents of recognized analytical reagent grade.

6.1 Standard gas mixtures

Nominally: 0,20 % carbon monoxide in nitrogen

Nominally: 0,75 % carbon monoxide in nitrogen

Gas standards with actual values within 25 % of the above are acceptable.

Other gas standards may be used, when alternative calibration procedures are adopted.

The precision of the concentration of gas standard mixture should be 3 % relative or better.

NOTE If carbon dioxide is also to be determined, it is recommended that nominally: 0,70 % carbon dioxide, and nominally: 2,00 % CO₂ standard gas mixes be used. In this case calibration gases may be a mixture of carbon monoxide and carbon dioxide, with concentrations as described above. Laboratory grade nitrogen or synthetic air is to be used for zeroing the analysers.

7 Sampling and preparation of cigarettes

7.1 General

Provide a laboratory sample (see 3.4), by using a suitable sampling scheme. Guidance may be found in ISO 8243.

7.2 Symbols

In 7.3, 7.4 and 8.1, the symbols listed in Table 1 are used.

Table 1 — Symbols used

Symbol	Variable
<i>N</i>	Number of cigarettes to be smoked.
<i>C</i>	Multiplying factor, value greater than 1, to allow for loss due to damage or selection procedures between initial sampling and smoking.
<i>n</i>	Number of replicate determinations of total sidestream smoke particulate matter.
<i>q</i>	Number of cigarettes smoked into the same sidestream smoke trap.
<i>P</i>	Total number of packets of cigarettes available.
<i>Q</i>	Total number of cigarettes available (laboratory sample, see 3.4).

7.3 Preparation of the cigarettes for smoking

If *N* cigarettes are to be smoked, $C \times N$ cigarettes should be prepared from *Q* for conditioning and butt marking. The multiplier *C* is usually at least 1,2 to provide extra cigarettes in case some are damaged. If a selection by mass or draw resistance (or any other parameter) is necessary because of the nature of the problem being studied, the selection is not to be considered as a method of reducing the number of cigarettes to be smoked. Therefore *C* will have to be much larger (experience suggests 2,0 to 4,0) depending on the selection process.

NOTE The precision data given in this method are based on eight replicates of three cigarettes. Any reduction in the number of replicates will affect the precision. It is not recommended to smoke less than five replicates.

The *N* cigarettes to be smoked will be tested in $n = N/q$ determinations if *q* cigarettes are smoked into one trap. As far as possible these *n* determinations should correspond to different test portions of the test sample. Selection of each test portion will depend upon the form of the test sample.

7.4 Selection of test portions of cigarettes

7.4.1 Selection of test portions from a bulk of *Q* cigarettes

If the test sample is in the form of a single bulk consisting of *Q* cigarettes, $C \times N$ cigarettes should be selected at random so that every cigarette has an equal probability of being chosen.
