To expedite distribution, this document is circulated as received from the committee secretariat. ISO Central Secretariat work of editing and text composition will be undertaken at publication stage.

Pour accélérer la distribution, le présent document est distribué tel qu'il est parvenu du secrétariat du comité. Le travail de rédaction et de composition de texte sera effectué au Secrétariat central de l'ISO au stade de publication.

THIS DOCUMENT IS A DRAFT CIRCULATED FOR COMMENT AND APPROVAL. IT IS THEREFORE SUBJECT TO CHANGE AND MAY NOT BE REFERRED TO AS AN INTERNATIONAL STANDARD UNTIL PUBLISHED AS SUCH.

IN ADDITION TO THEIR EVALUATION AS BEING ACCEPTABLE FOR INDUSTRIAL, TECHNOLOGICAL, COMMERCIAL AND USER PURPOSES, DRAFT INTERNATIONAL STANDARDS MAY ON OCCASION HAVE TO BE CONSIDERED IN THE LIGHT OF THEIR POTENTIAL TO BECOME STANDARDS TO WHICH REFERENCE MAY BE MADE IN NATIONAL REGULATIONS.

RECIPIENTS OF THIS DRAFT ARE INVITED TO SUBMIT, WITH THEIR COMMENTS, NOTIFICATION OF ANY RELEVANT PATENT RIGHTS OF WHICH THEY ARE AWARE AND TO PROVIDE SUPPORTING DOCUMENTATION.

## Foreword

ISO (the International Organisation for Standardisation) is a world-wide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organisations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardisation.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this International Standard may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

International Standard ISO 15646 was prepared by Technical Committee ISO/TC 85, Subcommittee SC 5.

# Re-sintering test for $\text{UO}_2$ , $(\text{U,Gd})\text{O}_2$ and $(\text{U,Pu})\text{O}_2$ pellets

## 1 Scope

This standard describes a procedure for measuring the densification of  $\text{UO}_2$ ,  $(\text{U,Gd})\text{O}_2$  and  $(\text{U,Pu})\text{O}_2$  pellets, achieved by heat treatment under defined conditions.

The densification of fuel in power operation is an important design feature. Essentially, it is dependent on structural parameters such as pore size, spatial pore distribution, grain size and, in the case of  $(\text{U,Gd})\text{O}_2$  and  $(\text{U,Pu})\text{O}_2$ , oxide phase structure. A thermal re-sintering test can be used to predict dimensional behaviour in the reactor because thermal densification is also dependent on these structural parameters, albeit in a differing manner in terms of quantity.

## 2 Brief description of procedure

The density of nuclear fuel pellets is measured before the re-sintering test. Afterwards, the pellets are subjected to heat treatment in a furnace under specified conditions with regard to temperature, time and sintering atmosphere. After cooling, the density is re-measured.

The oxygen/metal molar ratio should remain constant during the re-sintering test. The difference between the two density measurements shall be used to assess the thermal stability of the pellet lot.

## 3 Incidents

Minor chipping can occur during pellet handling. Densities of visibly chipped pellets must not be measured using the geometric method, as the results will be inaccurate.

Densities of such chipped pellets can be measured using the buoyancy method.

## 4 Apparatus

Specifically for  $(\text{U,Pu})\text{O}_2$ , all operations shall be performed in glove boxes.

### 4.1 Equipment for measuring density

The same method shall be used before and after resintering of pellet.

In the two following paragraph (§ 4.1.1 and 4.1.2), two different measurement methods are mentioned as example. Other methods can be used if they meet the customer uncertainty requirement.

#### 4.1.1 Geometric measurement of density

Dial test indicator or micrometer with precision of 1  $\mu\text{m}$  in order to measure the diameter and the height. Balance with precision 1 mg or better.

#### 4.1.2 Measurement of density using buoyancy method

Reference ISO Standard 3369

## 4.2 Heat treatment furnace

A programmable furnace able to reach temperatures of about 1 800°C under gas scavenging shall be used. It is advisable to use two different thermocouples for furnace control and monitoring.

## 5 Reagents

### 5.1 Gas

The furnace gas shall ensure a constant Oxygen/heavy metal ratio. Usually, the re-sinter test will employ a similar furnace atmosphere to that used when the pellets were sintered during manufacture. The test furnace shall be qualified to prove that the Oxygen/heavy metal ratio of the fuel tested does not change by more than  $\pm 0,005$ . The following are examples of furnace atmospheres that can be used.

Note: heavy metal = U or U+Pu or U+Gd depending the concerned product

*For UO<sub>2</sub> fuel*

Pure hydrogen ( Purification better than a volume fraction of 99,99%)

Mixture of noble gas ( Purification better than a volume fraction of 99,99%) with at least 3% of hydrogen

*For MOX fuel*

Pure argon ( Purification better than a volume fraction of 99,99%).

Pure argon (Purification better than a volume fraction of 99,99%) with 7% hydrogen, humidified as required to maintain stoichiometry.

Argon with 4% hydrogen and CO<sub>2</sub> as required to maintain stoichiometry.

Dry cracked ammonia gas (75% H<sub>2</sub>-25%N<sub>2</sub> by volume with gas mixture purity of at least 99.9% by volume and a dew point less than -40 deg. C)

### 5.2 Degassed water

Distilled and degassed (e.g. by boiling) water as buoyancy test fluid, or distilled water to which a wetting agent (soap) has been added to eliminate any micro bubbles.

## 6 Sampling

In case of using geometric method for the density measurement, the selected pellets shall be free of any visible defects liable to bias the density measurements (e.g. chipping, cracking, thumbnail cracks, etc.). In case of using buoyancy method for the density measurement, the pellets with these visible defects can be kept.

## 7 Procedure

### 7.1 Density measurements before heat treatment

The density of the fuel pellets has to be measured prior the heat treatment. Of all the procedures available, geometric density measurements and the buoyancy method have proved most satisfactory for routine quality control inspection. The geometric method is preferable where the pellets have a large fraction of open pores (i.e. pores having a connection to the pellet surface). Pellets that have sustained chipping are better measured using the buoyancy method or the penetration immersion method as defined in ISO 9278: (E)

### 7.2 Heat treatment

Following the density measurement, the pellets, after position identification to ensure traceability, are subjected to heat treatment in the furnace using the following parameters:

*Heating rate:* <15 °C/min (at higher rates the pellets could burst). A heating rate of 5°/mn is recommended in order to be sure not to burst the pellets.

*Heat treatment temperature:* shall be specified jointly by the customer/fuel designer and the fuel vendor. Temperatures of the order of 1 700°C are generally recommended.

*Treatment time:* shall be specified jointly by the customer/fuel designer and the fuel vendor. As example residence time of the order of 24 h is generally applied.

*Treatment atmosphere:*

For UO<sub>2</sub> pellets, pure hydrogen (≥99,9%) or mixtures of noble gas (≥99,9%) and hydrogen with a hydrogen content of not less than a volume fraction of 3 %.

For (U, Gd)O<sub>2</sub> and (U, Pu)O<sub>2</sub> pellets, a shift in stoichiometry of pellets will occur during treatment when using dry hydrogen or dry hydrogen/noble gas mixtures. This can be avoided by using a gas atmosphere with a suitable oxygen partial pressure which keeps the stoichiometry constant during re-sintering. Adjusting the oxygen partial pressure can be done by admixing CO<sub>2</sub> in appropriate proportions to the re-sinter atmosphere or by using wet hydrogen or wet hydrogen/noble gas mixtures. A pure argon atmosphere can be used.

NOTE. For (U, Gd)O<sub>2</sub> pellets, if necessary, an adjustment of the initial Oxygen/heavy metal (U+Gd) ratio can be performed by a heat treatment of the pellets at 150°C in air during a holding time of 5 h. The heat up rate shall be low enough to avoid cracking especially at high Gd contents. The annealing step ensures the adjustment of the equilibrium stoichiometry for (U,Gd)O<sub>2</sub> fuel pellets with a Gd content up to 10% by mass.

*Cool down rate:* < 15°C/min.

*Records:* For each re-sintering run, the temperature profile is recorded. If the temperature profile satisfies the heat treatment condition specified above, the results of the re-sintering test are accepted.

### 7.3 Density measurements after heat treatment

Following cooling, the pellets are removed from the furnace and their densities shall be re-measured with the same method used before the heat treatment.

## 8 Evaluation

The re-sinter densification is determined by calculating the difference between the densities before and after the heating treatment. When measuring density, the mass of the pellets shall be measured prior to and upon completion of the heat treatment.

To check that the ratio O/M has not changed in excess of the tolerance of  $\pm 0,005$ , it is necessary to verify that the pellet mass difference, before and after the heat test, is below the following limit:

$$\text{Mass difference} \leq \frac{\text{Mass pellet before test}}{\text{Oxide molar mass}} \times \text{O}_2 \text{ molar mass} \times \text{O/M Changing tolerance} \quad \text{Eq.1}$$

The demonstration of the formula (Eq 1) is in attached 1.  
In case of MOX pellets, the calculation is:

$$\text{Mass difference} \leq \frac{\text{Mass pellet before test}}{(238 + 2 \times 16)} \times (2 \times 16) \times 0,005 \quad \text{Eq.2}$$

$$\text{Mass difference} \leq 0,00059 \times \text{Mass pellet before test}$$

It is good practice to monitor the mean change of all measured pellet mass as a result of re-sintering and check that this does not differ statistically significantly from zero. A significant change would indicate a fault with the furnace atmosphere (e.g. due to leakage). The absolute value of the difference from zero should be lower than the maximum mass difference accepted for one pellet (See Eq.1).

The density can be calculated through the ratio of measured density to the theoretical density.

(Note) The density measurement shall be made by the specified methods as mutually agreed upon between the buyer and the seller (refer to ISO 9278)

## 9 Precision of the procedure

The precision of the overall procedure is determined by the precision of the method used to measure density. The repeatability standard deviation in DIN 55 350 for the buoyancy and the penetration immersion method (in turn defined in ISO 9278 : (E)) is 0,1%.

Nevertheless, due to the difficulty to weigh a pellet in liquid, in the course of buoyancy density measurement method, the uncertainty can reach 0,2%.

## 10 Test report

The test report with reference to this standard shall contain the following information:

- all data necessary for identification of the sample
- result of test
- location and date of test.
- record profile of temperature

### Relation between pellet mass evolution and O/M ratio evolution

Assumption 1 : It is considered that  $\text{UO}_2$  pellets and MOX pellet are equivalent with regard to the O/M ratio evolution because MOX pellet contains around 90% of  $\text{UO}_2$  and because the molar weight of U is near the one of Pu.

Assumption 2 : The maximum acceptable evolution of the O/M ratio during resintering test is 0,01

Chemical equation :

Molar balance :

$$n_{\text{UO}_2} = n_{\text{UO}_{2,01}}$$

$$\frac{m_{\text{UO}_2}}{M_{\text{UO}_2}} = \frac{m_{\text{UO}_{2,01}}}{M_{\text{UO}_{2,01}}}$$

$$m_{\text{UO}_{2,01}} = \frac{m_{\text{UO}_2}}{M_{\text{UO}_2}} \times M_{\text{UO}_{2,01}}$$

Mass difference :

$$\Delta m = m_{\text{UO}_{2,01}} - m_{\text{UO}_2}$$

$$\Delta m = \frac{m_{\text{UO}_2}}{M_{\text{UO}_2}} \times M_{\text{UO}_{2,01}} - m_{\text{UO}_2}$$

$$\Delta m = m_{\text{UO}_2} \times \left( \frac{M_{\text{UO}_{2,01}}}{M_{\text{UO}_2}} - 1 \right)$$

$$\Delta m = m_{\text{UO}_2} \times \left( \frac{M_{\text{UO}_2} + 0,01 \times M_{\text{O}} - M_{\text{UO}_2}}{M_{\text{UO}_2}} \right)$$

$$\Delta m = m_{\text{UO}_2} \times \frac{0,01 \times M_{\text{O}}}{M_{\text{UO}_2}}$$

$$\Delta m = m_{\text{pastille}} \times \frac{0,01 \times 16}{270}$$
