Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see www.iso.org/patents).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation on the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the WTO principles in the Technical Barriers to Trade (TBT) see the following URL: Foreword - Supplementary information

The committee responsible for this document is ISO/TC 123, *Plain bearings*, Subcommittee SC 7, *Special types of plain bearings*.

Introduction

For crosshead pin bearings, with which a shaft oscillates when a load is applied mainly in a downward direction, it is difficult to generate an appropriate lubricating film; therefore, they are subject to unfavourable lubricating conditions. For better lubrication of crosshead pin bearings, which have a high rate of damage, two types of bearing structures are mainly used as oil supply methods for sliding surfaces at present. The characteristics of those bearings are compared and the concept of design approaches is standardized.

Plain bearings — Lubrication characteristics of crosshead pin bearings for low-speed marine diesel engines

1 Scope

This Technical Report specifies lubrication characteristics of grooves and pockets on crosshead pin bearings for low-speed marine diesel engines.

It is applicable to the design of axial oil groove and pocket types as an oil supply method.

2 Crosshead pin bearing and its symbols

The crosshead pin bearing and changes in specific load and angular velocity during one cycle are schematically illustrated in [Figures 1](#) and [2](#). [Table 1](#) shows the symbols and their descriptions.

Table 1 — Symbols and their descriptions

Symbol	Description
e	eccentricity
h _{min}	minimum oil film thickness
l	subtended taper length
L	axial width
O _b	center of bearing
O _j	center of journal
p	oil film pressure
P1	pad 1
P2	pad 2
P3	pad 3
\bar{P}_r	specific load
r	shaft radius
F	bearing load
α	circumferential pitch angle
β	circumferential width angle
γ	taper depth
φ	oscillation angle
ϕ	attitude angle
θ	circumferential angular coordinate
$\theta_2 - \theta_1$	effective angular extent of bearing arc
ω	angular velocity

3 Oil supply method on bearing sliding surfaces

There are two oil supply methods. One is for bearings with a few (normally four) axial grooves. Oil is supplied to the sliding surface at normal pressure through these oil grooves. The other is for bearings with two oil pockets symmetrically located relative to the central part of each bearing. Oil is supplied to the oil pockets at high pressure to provide a hydrostatic bearing mechanism (see [Figure 3](#)).

4 Shape of a bearing

4.1 Bearing inside diameter, bearing width, height, circumferential groove, and an upper bearing

The diameter of a crosshead pin is set by consideration of strength design taking into account such as cylinder bore diameter and explosion pressure. The inside diameter of the bearing is based on the diameter of its crosshead pin. The bearing width is set within the allowable specific pressure range for its bearing material in consideration of the durability and strength of the material. Normally, single wide (integral structure) bearings are commonly used with respect to each cylinder. Some bearings may be axially divided into two parts for the reason of production of their bearing materials. The height of the bearing should be set to ensure adequate interference fit. The height measurement method is the same as for smaller sized half-bearings. The crosshead housing can be checked for deformation due to the tightening of the bearing by conducting an assembly test using a housing (it might affect bearing clearance). In the case of a bearing with more than one axial groove, it may be provided with a circumferential groove around (part of) the entire circumference. The upper bearing on the unloaded side is provided with a relatively wide opening to allow the crosshead pin, which is connected to a piston rod, and the crosshead pin bearing to oscillate relative to each other.
