Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

ISO 17731 was prepared as Standard CIE S 021/E by the International Commission on Illumination, which has been recognized by the ISO Council as an international standardizing body. It was adopted by ISO under a special procedure which requires approval by at least 75 % of the member bodies casting a vote, and is published as a joint ISO/CIE edition.

The International Commission on Illumination (abbreviated as CIE from its French title) is an organization devoted to international cooperation and exchange of information among its member countries on all matters relating to the science and art of lighting.

ISO 17731 was prepared by CIE Technical Committee 4-45, *Performance Assessment Method for Vehicle Headlamps*.

Foreword

Standards produced by the Commission Internationale de l'Eclairage are concise documents on aspects of light and lighting that require a unique definition. They are a primary source of internationally accepted and agreed data which can be taken, essentially unaltered, into universal standard systems.

This CIE Standard has been prepared by CIE Technical Committee 4-45¹ "Performance Assessment Method for Vehicle Headlamps" and is derived from CIE 188:2010, which was produced by the same committee.

Vehicle Headlighting Systems Photometric Performance - Method of Assessment

1 Scope

This Standard specifies a method to consistently assess the photometric performance of vehicle headlighting systems to enable the performance of different systems to be compared. The requirements are given in relation to road scene illumination and the limitation of glare, and the performance is assessed using parameters relevant to lane guidance and the detection of pedestrians and objects.

The Standard includes a measurement and calculation procedure. It does not specify the format of an assessment report.

3 Terms and Definitions

For the purposes of this document the terms and definitions given in the International Lighting Vocabulary (CIE DS 017.2/E:2009) and the following apply:

3.1

headlighting system

a full set of headlights as installed to a vehicle

3.2

nearside

for traffic following the right-hand rule of the road, the right side of the vehicle

3.3

offside

for traffic following the right-hand rule of the road, the left side of the vehicle

NOTE With regard to the performance of the passing beam it is necessary to define whether the traffic flow is for right-hand or left-hand rule of the road. For the purposes of this Standard it is assumed that the traffic is following the right-hand rule of the road (as in mainland Europe and USA for example) and all reference to features of the beam pattern and photometric performance is related to this. In the case of traffic following the left-hand rule of the road (as in Japan and the UK for example) a reference to a feature on the right in this document should be transformed to refer to an identical feature translated to the left side.

4 Headlight Performance

4.1 General

The assessment method given in this Standard is a means of evaluating headlighting system performance, to enable the performance of different systems to be compared. It uses techniques that produce repeatable results, and has been developed to give correspondence with the subjective impressions of the driver.

When assessing the compliance of a headlighting system to safety regulations or standards with this method, it is solely the photometry of the passing beam and driving beam that is evaluated using calibrated equipment in the photometric laboratory.

NOTE 1 In service, the photometric performance of the headlight is influenced by a number of factors that will cause the actual performance to differ from that defined in regulations or standards. These include mounting height, supply voltage/operating current, beam alignment, variations in light source geometry and the headlight optical system, luminous flux, etc.

Vehicle headlights illuminate the road scene ahead of the vehicle in order to provide guidance for the driver to retain control of the vehicle through adequate illumination of road markings, the edges of the road and features such as verges, trees and road signs, and to provide early warning of the presence of obstacles including pedestrians and other road users.

It is also necessary that headlighting system performance is such that glare to vehicles travelling in the opposite direction is controlled.

NOTE 2 Reflected glare in rear view mirrors caused by the headlights of following vehicles is not taken into account, as technologies exist to reduce the reflectivity of the mirrors.

4.2 Assessment Requirements

The vertical illuminance² provided by the headlighting system shall be determined both at the road surface and at a horizontal plane located 250 mm above the road surface, using the assessment procedure and measurement and calculation procedure described in Clauses 6 and 7 respectively. To ensure repeatability of results and to avoid interpolation errors when transforming data between matrices, the measurements and calculations shall exactly follow the procedures set out in these clauses.

NOTE The height of 250 mm corresponds to the mid-point of the leg of an average pedestrian.

4.3 Assessment of Simulated Headlights

During the development of headlights it may be necessary to produce a performance assessment of a new model at the design stage before tooling has been manufactured. Software packages can be used to provide simulations of photometric data for the design, produced from CAD data. This simulated photometric data can be used as an input into the measurement and calculation procedure described in Clause 7, replacing the photometric measurement described in 7.1 a) to d). The output from the simulation software shall comply with the requirements given in 7.1 e).

5 Beam Assessment Parameters

The assessment of the passing beam takes account of the following requirements:

- range for guidance,
- range for pedestrian detection,
- width for lane guidance,
- visibility on curves,
- width for pedestrian detection at intersections,
- opposing glare.

² In the following, if not indicated otherwise, vertical illuminances are meant when speaking of illuminances.

The assessment of the driving beam takes account of the following requirements:

- range for pedestrian detection, lane guidance and visibility,
- width for pedestrian detection at intersections.

The assessment for both beams includes the calculation of the total projected luminous flux, as an indication of the optical efficiency of the system.

6 Assessment Procedure

6.1 Basis of the Procedure

The procedure is based upon laboratory measurements of headlights under controlled conditions (calibrated light source, vehicle operating voltage as defined in 7.2 d, initial aim according to 7.2 c) using a defined format for the data including the angular increments of the measurement points. Using these data, aspects of the headlight performance are evaluated as detailed in 6.2 to 6.3. In all cases, the illuminance and luminous intensity values being assessed are derived from a combination of the individual photometric data measured for each component of the headlighting system. These values are combined taking account of the mounting height, separation and aim specified for the particular vehicle to which the system is installed. The method of combining the data is described in Clause 7.

6.2 Passing Beam Illumination

6.2.1 Summary of Process

Illumination of the road scene by the passing beam shall be assessed by evaluating the performance of the headlighting system as summarised in Table 1.

NOTE The zones are for traffic following the right-hand rule of the road.

ISO/FDIS 17731
Table 1 – Aspects of passing beam road scene illumination to be assessed

Zone (see Figures 1 to 6)	Purpose	Assessment Method
A, B	Range for lane guidance	See explanation in 6.2.2 and Figures 1, 2, 3 and 4
C	Range along the offside verge for pedestrian detection	See explanation in 6.2.3 and Figure 5
D	Width for lane guidance and visibility on curves	See 6.2.5 and Figure 6 Evaluate arithmetic mean value of the width of the 3,0 lx line at 30 m, 40 m and 50 m in front of the vehicle at the road surface. Individual width values are calculated from the lane centre line to the offside and nearside of the vehicle.
E	Width for pedestrian detection at intersections	See 6.2.5 and Figure 6 Evaluate arithmetic mean value of the width of the 3,0 lx line at 10 m and 20 m from the car on a plane located at 250 mm above the road surface. Individual width values are calculated from the lane centre line to the offside and nearside of the vehicle
Whole beam	Luminous flux	See 6.2.4 Total luminous flux (lumen) within a vertical zone 5° up to 15° down, 45° left to 45° right
