iTeh STANDARD PREVIEW
(standards.iteh.ai)

This Technical Specification (CEN/TS) was approved by CEN on 3 December 2015 for provisional application.

The period of validity of this CEN/TS is limited initially to three years. After two years the members of CEN will be requested to submit their comments, particularly on the question whether the CEN/TS can be converted into a European Standard.

CEN members are required to announce the existence of this CEN/TS in the same way as for an EN and to make the CEN/TS available promptly at national level in an appropriate form. It is permissible to keep conflicting national standards in force (in parallel to the CEN/TS) until the final decision about the possible conversion of the CEN/TS into an EN is reached.

CEN members are the national standards bodies of Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, Former Yugoslav Republic of Macedonia, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, Switzerland, Turkey and United Kingdom.

European foreword

This document (CEN/TS 15901-14:2016) has been prepared by Technical Committee CEN/TC 227 “Road materials”, the secretariat of which is held by DIN.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. CEN [and/or CENELEC] shall not be held responsible for identifying any or all such patent rights.

According to the CEN-CENELEC Internal Regulations, the national standards organizations of the following countries are bound to announce this Technical Specification: Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, Former Yugoslav Republic of Macedonia, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, Switzerland, Turkey and the United Kingdom.

CEN/TS 15901-14:2016 (E)**1 Scope**

This Technical Specification describes a method for determining the wet road skid resistance of a surface by measurement of the longitudinal friction coefficient LFCN. The described method is also used to determine the skid resistance on a surface covered by ice or snow.

The method provides friction coefficient measurements of the pavement by using an electrically braked test wheel.

ViaFriction can operate in the following modes:

- Fixed slip: The slip ratio is fixed. The slip ratio can be set to a value from 1 % to 75 %.
- Fixed slip speed: The slip speed is fixed. The slip speed has to be lower than the vehicle speed.
- Variable slip: The test wheel is braked from 0 % to 75 % slip ratio recording F 30, F 60 and the slip ratio/friction curve.

The test tyre is dragged over a pre-wetted pavement under controlled speed conditions while the test tyre is parallel to the direction of motion and perpendicular to the pavement. Skid resistance measurement on winter roads do not require pre-wetted pavement.

To determine the macrotexture of the pavement surface a laser system can be added. This system is placed in front of the towing vehicle in order to measure the macrotexture (mean profile depth — MPD) on dry pavements and on the same path as the skid resistance measurement is done. The standard for this measurement and the device is described in EN ISO 13473-1.

ISO 13473-2, *Characterization of pavement texture by use of surface profiles — Part 2: Terminology and basic requirements related to pavement texture profile analysis*

ASTM 1551, *Standard Specification for Special Purpose, Smooth-Tread Tire, Operated on Fixed Braking Slip Continuous Friction Measuring Equipment*

3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

3.1

wet road skid resistance

property of a trafficked surface that limits relative movement between the surface and the part of a vehicle tyre in contact with the surface, when lubricated with a film of water

Note 1 to entry: Factors that contribute to skid resistance are tyre pressure, contact area, tread pattern and rubber composition: the alignment, texture, surface contamination and characteristics of the road surface, vehicle speed and weather conditions.

Note 2 to entry: The skid resistance of a surface in Europe varies seasonally. Generally, wet skid resistance is higher in winter as a result of the effects of wet detritus and the effects of frost and wear by tyres on microtexture and macrotexture. Wet skid resistance is lower in summer as a result of dry polishing by tyres in the presence of fine detritus.

Note 3 to entry: The change in skid resistance of a surface in service is affected by the volume of traffic and the composition of the traffic, i.e. cars, buses, commercial vehicles of different sizes, as the tyres of these vehicles polish and/or wear the surfacing material in different ways. The geometry of the road will affect the change in skid resistance. Generally, tyres polish less on straight roads than on bends.

Note 4 to entry: Where the surface contains aggregate with a coating of binders, e.g. bitumen, resin or Portland cement, the skid resistance can change as the coating is worn away by tyres.

3.2

dry road skid resistance

property of a trafficked surface that limits relative movement between the surface and the part of a vehicle tyre in contact with the surface. The contact is not lubricated with a film of water

3.3

skid resistance

characterisation of the friction of a road surface when measured in accordance with a standardised method

3.4

friction coefficient

μ

ratio between the horizontal force in the direction of the motion that can be activated between the test wheel and the wet pavement and the vertical wheel load accomplished under controlled slipping conditions

Note 1 to entry: The controlled slipping condition is achieved by an electrical brake system. If the vehicle is in motion, the test wheel slides or slips in the forward direction.

3.5

friction

resistance to relative motion between two bodies in contact, the frictional force being the force, acting tangentially in the contact area, which is measured by a friction-measuring device

3.6

slip ratio

slip speed divided by the vehicle speed

CEN/TS 15901-14:2016 (E)**3.7****fixed slip speed**

this is a fixed slip where the slip speed is configurable and independent of the vehicle speed. The vehicle speed has always to be higher than the configured fixed slip speed

3.8**F 30**

friction value at 30 km/h slip speed

3.9**F 60**

friction value at 60 km/h slip speed

3.10**LFCN**

longitudinal friction coefficient measured with the ViaFriction

3.11**macrotexture**

deviation of a pavement from a true planar pavement with characteristic dimensions along the pavement of 0,5 mm to 50 mm, corresponding to texture wavelengths with one-third-octave bands including the range 0,63 mm to 50 mm centre wavelengths

Note 1 to entry: Peak to peak amplitudes normally vary in the range 0,1 mm to 20 mm.

Note 2 to entry: Macrotexture is a major factor influencing skid resistance at high speeds but it also has an effect at low speeds.

3.12**Mean Profile Depth****MPD**

descriptor of macrotexture, obtained from a texture profile measurement as defined in EN ISO 13473-1 and ISO 13473-2

SIST-TS CEN/TS 15901-14:2016
<https://standards.iteh.ai/catalog/standards/sist/77f0e629-57ed-45e8-8cd2-470c61ac550b/sist-ts-cen-ts-15901-14-2016>

3.13**calibration**

periodic adjustment of the offset, the gain and the linearity of the output of a measurement method so that all the calibrated devices of a particular type deliver the same value within a known and accepted range of uncertainty, when measuring under identical conditions within given boundaries or parameters

3.14**retaliation friction devices**

type of friction device fitted to vehicles

Note 1 to entry: When the vehicle brakes are used with full force for a short period, the speed change or deceleration is used to calculate the friction.

Note 2 to entry: This type of friction device is used on winter road surfaces covered with ice or snow.

3.15**braking force coefficient**

ratio between the longitudinal frictional force and the load on the test wheel

Note 1 to entry: The test wheel mass which is without dimension.

3.16 vehicle speed

speed at which the device traverses the test surface

3.17 slip speed

relative speed between the test wheel and the pavement in the contact area

3.18 wheel path

part of the pavement where the majority of the vehicle wheel passes are concentrated

Note 1 to entry: The wheel path is not a fixed location on a pavement surface. On a worn pavement, the wheel path can usually be identified easily visually. On a new laid surface, the position of the wheel path needs to be estimated by experienced operators.

Note 2 to entry: For special circumstances such as acceptance tests, a particular path can be defined, for example (700 ± 150) mm from the edge of the running lane of a road.

3.19 theoretical water film thickness

thickness of a water film between a test wheel and a test pavement, assuming the pavement has zero texture depth

3.20 winter road

road surface having a temperature below $+5^{\circ}\text{C}$

Note 1 to entry: The road surface may be covered by snow and ice. The wet road skid resistance cannot be measured due to the risk of depositing ice on the road.

3.21 summer road

road surface having a temperature of 5°C or more where wet road skid resistance can be measured

4 Recommended uses

The ViaFriction is used in the following fields of application:

- road network monitoring (Pavement Management measuring wet road skid resistance on summer roads and measuring dry road skid resistance on winter roads);
- approval of new surfacing;
- measurements after traffic accidents;
- investigation of surface skid resistance;
- comparative measurements among different devices;
- testing of tyres.
