Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see www.iso.org/patents).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation on the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT) see the following URL: www.iso.org/iso/foreword.html. (standards.iteh.ai)

This document was prepared by Technical Committee ISO/131, *Fluid power systems*, Subcommittee SC 6, *Contamination control*.

Introduction

In hydraulic fluid power systems, power is transmitted through a liquid under pressure within a closed circuit. The liquid is both a lubricant and power-transmitting medium. The presence of solid particulate contamination interferes with the ability of the hydraulic liquid to lubricate and causes wear to the components. The extent of this form of contamination has a direct bearing on the performance and reliability of the system and needs to be controlled to levels that are considered appropriate for the system concerned. This level is called the required cleanliness level (RCL) and the level for an individual system depends upon the contaminant sensitivity of the system and the level of reliability required by the user. It therefore varies from application to application and within common system types.

In the past, the selection of the RCL was arbitrary and based on either the system designer's past experience or on third-party recommendations that were based upon their experience. Rarely did the selection reflect current fluid cleanliness requirements. Furthermore, as the selection was subjective, there was not any consistency in the RCL recommended by the various parties involved in the selection. The end result was that the user of the RCL would be confused and select an incorrect RCL. This fact was recognised by the British Fluid Power Association (BFPA) in 1999[1], and it developed a method for selecting an RCL which was based upon the requirements of an individual system and user (see the Bibliography). The rationale behind the development of this method is given in [Annex A](#). This has since been adopted as Norwegian national standard NS 2085[2].

The emphasis on fluid cleanliness has made the RCL an important parameter in the management of cleanliness in hydraulic systems. The RCL sets the standard for cleanliness throughout the manufacturing process, through the assembly and commissioning stages, and in service. It also is instrumental in ensuring that the correct filtration level is achieved in the operating system. The RCL calculated by this method is used in ISO/TR 15640[3] to assist in the selection of filters.

This document has been developed to provide a uniform and consistent procedure for selecting the RCL for a particular system. It takes the user of this procedure through a series of conditions that best describe the system for which the RCL is required and the RCL is selected on this basis.

Hydraulic fluid power — Method for determining the required cleanliness level (RCL) of a system

1 Scope

This document specifies a method of determining the required cleanliness level of a hydraulic system, that is, the most appropriate fluid cleanliness level for an operating hydraulic system based upon the individual requirements of that system.

It is applicable to systems where the level of fluid cleanliness is expressed in accordance with ISO 4406, although conversion to other contamination coding systems is possible.

It is applicable to both high and low pressure fluid power systems and also lubrication systems.

It does not include the effects of soft deformable particles that can be generated by thermal decomposition of the hydraulic fluid.

3 Terms and definitions

For purposes of this document, the terms and definitions given in ISO 5598 and the following apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

- ISO Online browsing platform: available at www.iso.org/obp
- IEC Electropedia: available at www.electropedia.org

3.1

contamination code

set of numbers used as a shorthand method for describing the particle size distribution of contaminants in hydraulic fluid

[SOURCE: ISO 5598:2008, 3.2.129]

Note 1 to entry: ISO 4406 contamination codes are used throughout this document.

3.2

contaminant sensitivity

extent to which a component is adversely affected by the presence of particulate contamination

3.3

duty cycle

characteristic of a hydraulic system which defines the operational pressure level and the rate of change in pressure

**3.4
field contamination monitor**

instrument that automatically evaluates the general level of fluid cleanliness, usually by either the filter blockage technique or the light blockage technique

**3.5
off-line contamination analysis**

analysis of a fluid sample by an instrument that is not directly connected to the hydraulic system

[SOURCE: ISO 5598:2008, 3.1.128]

**3.6
on-line contamination analysis**

analysis performed on fluid supplied directly to the instrument from a major flow line in the hydraulic system

[SOURCE: ISO 5598:2008, 3.2.480]

Note 1 to entry: The instrument can either be permanently connected to the flow line or connected prior to analysis.

**3.7
particle size**

characteristic dimension of a particle, that defines the magnitude of the particle in terms of a physically measurable dimension related to the analysis technique used, such as the longest dimension or the equivalent spherical diameter

**3.8
qualitative data**

data that have less precision or accuracy than data obtained using quantitative methods and which is usually expressed in codes rather than actual numbers

**3.9
required cleanliness level
RCL**

hydraulic fluid cleanliness level required for a system or process

Note 1 to entry: For the purposes of this document, this is expressed in accordance with ISO 4406.

**3.10
working pressure range**

range of pressures between the limits within which a system or sub-system is intended to operate in steady-state operating conditions

[SOURCE: ISO 5598:2008, 3.2.780]

4 Principle of the method

The user of this document systematically examines six operational characteristics or requirements and selects the condition that best describes that system or the user's requirements. A weighting is assigned to each selected condition, and this is summated into a system weighting. This system weighting is then used to select the RCL. The chart linking the RCL with the system weighting has been developed from practical examples and is given in [Figure 1](#).

NOTE In practice, the RCL is initially obtained by the system flushing process, and then maintained by the system filtration.

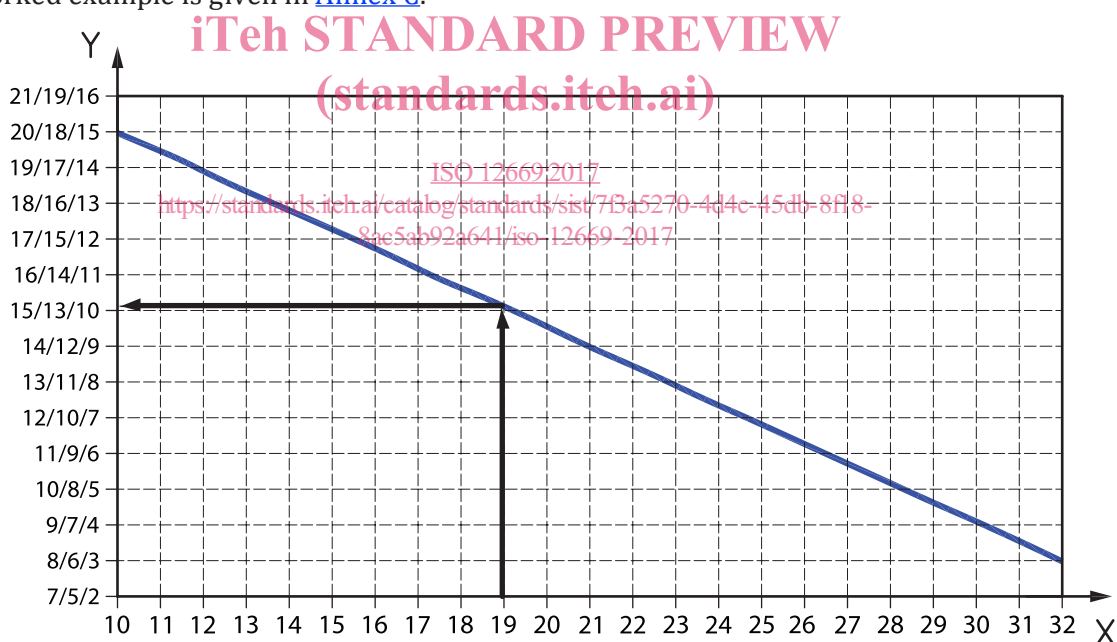

5 Selection of the RCL

5.1 General

Each of the six operational parameters defined in 5.3 to 5.8 are subdivided into different levels, and a relative weighting is given to reflect their impact on either the particle generation rate of the component or the effect that the particulate can have on it. To assist the user of this document, the various categories are illustrated with practical examples. The impact of the parameter is also explained.

5.2 Procedure

- Start at 5.3, and select from Table 1 the operational conditions that best describe the system whose RCL is being determined. Record that weighting on a suitable pro forma sheet; an example is given in Annex B.
- Repeat the process stated in 5.2 a) for 5.4 through to 5.8, and sum all weightings recorded. If the sum of all weightings is <10, use as the corresponding weighting 10. If the sum of all weightings is >32, use 32 as the corresponding weighting.
- Use Figure 1 to locate the corresponding weighting on the x-axis and draw a vertical line upwards to intersect the grade line.
- Draw a horizontal line leftwards to intersect an ISO 4406 code on the y-axis; this code is the RCL. A worked example is given in Annex C.

Key

- X total weighting
Y maximum ISO 4406 code

Figure 1 — Relationship of total weighting and ISO 4406 codes used to derive the required cleanliness level (RCL)

The ISO 4406 codes stated assume a fixed particle size distribution which might or might not be duplicated in service. For example:

- at the cleaner levels/lower scale numbers [less than ISO 4406 scale number 10 at 6 $\mu\text{m}(\text{c})$], the difference in scale numbers between both 4 $\mu\text{m}(\text{c})$ and 6 $\mu\text{m}(\text{c})$ and also 6 $\mu\text{m}(\text{c})$ and 14 $\mu\text{m}(\text{c})$ can be greater than stated as the numbers of particles at the higher sizes approach zero.

- at the dirtier levels/higher scale numbers [greater than ISO 4406 scale number 17 at 6 µm(c)], the difference in scale numbers between 4 µm(c) and 6 µm(c) can be 3 or more ISO 4406 scale numbers due to limited capture of smaller particles by the system filters.

In all cases, the ISO scale number at 6 µm(c) shall be taken as the reference.

The grade line has been drawn using data obtained from the on-line analysis of systems as this method of analysis excludes environmental contamination introduced when the sample is collected in sample bottles for off-line analysis (see Annex D). As the use of sample bottles and subsequent off-line analysis can introduce relatively large amounts of particulate contamination, this process is considered unsuitable for cleanliness levels better than ISO 4406 Code 14/12/9.

5.3 Weightings for working pressure and duty cycle

The normal working pressure and duty cycle, which reflects the severity of change, both in magnitude and frequency of the pressure experienced in the system, shall be taken into account in accordance with the weighting specified in Table 1.

Table 1 — Weightings for working pressure and duty cycle

Duty cycle		Working pressure				
Level	Description	≤ 6 MPa (≤ 60 bar)	> 6 MPa (> 60 bar) ≤ 16 MPa (≤ 160 bar)	> 16 MPa (> 160 bar) ≤ 25 MPa (≤ 250 bar)	> 25 MPa (> 250 bar) ≤ 40 MPa (≤ 400 bar)	> 40 MPa (> 400 bar)
Light	Continuous duty with little variation in working pressure	1	1	2	3	4
Medium	Moderate variations in working pressure	2	3	4	5	6
Heavy	Large variations in working pressure from zero to maximum	3	4	5	6	7
Severe	Large variations in working pressure from zero to maximum, with high frequency pressure transients (for example, pressure traces seen in power presses and punching machines)	4	5	6	7	8

5.4 Weightings for component contaminant sensitivity

The sensitivity of components to solid particulate contaminant shall be taken into account in accordance with the weighting specified in Table 2.

Table 2 — Weightings for component contaminant sensitivity

Sensitivity level	Example components	Weighting
Minimal	Ram pumps	1
Below average	Low performance gear pumps, manual valves, poppet valves	2
Average	Vane pumps, electro-hydraulic spool valves, high performance gear pumps	3
Above average	Piston pumps, proportional control valves	4
High	Servo-valves in industrial applications, high pressure proportional control valves	6
Very high	High performance servo-valves	8

5.5 Weightings for system life expectancy

The expected life of the system shall be taken into account in accordance with the weighting specified in [Table 3](#).

Table 3 — Weightings for system life expectancy

System life expectancy (h)		Weighting
≥ 0	≤ 1 000	0
> 1 000	≤ 5 000	1
> 5 000	≤ 10 000	2
> 10 000	≤ 20 000	3
> 20 000	≤ 40 000	4
> 40 000	—	5

ISO 12669:2017

5.6 Weightings for total cost of component replacement

The total cost of component replacement shall be taken into account in accordance with the weighting specified in [Table 4](#).

Table 4 — Weightings for total cost of component replacement

Total cost of component replacement	Examples	Weighting
Low	Manifold-mounted valves, inexpensive pumps	1
Average	Line-mounted and modular valves	2
High	Cylinders, proportional control valves	3
Very high	Large piston pumps; large high-torque, low-speed motors, high performance servo components	4

5.7 Weightings for cost of downtime

The cost of downtime shall be taken into account in accordance with the weighting specified in [Table 5](#).

Table 5 — Weightings for cost of downtime

Cost of downtime	Examples	Weighting
Low	Equipment that is not critical to production or operation	1
Average	Equipment in plant with small to medium volume production	2
High	Equipment in plant with high volume production	3
Very high	Equipment with very high downtime costs, e.g. certain steel mill equipment	4
