Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2. www.iso.org/directives

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received. www.iso.org/patents

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation on the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the WTO principles in the Technical Barriers to Trade (TBT), see the following URL: [Foreword - Supplementary information](#)

The committee responsible for this document is ISO/TC 206, *Fine ceramics (advanced ceramics, advanced technical ceramics)*.

Fine ceramics (advanced ceramics, advanced technical ceramics) — Mechanical properties of ceramic composites at room temperature — Determination of elastic properties by an ultrasonic technique

1 Scope

This International Standard specifies an ultrasonic method to determine the components of the elasticity tensor of ceramic matrix composite materials at room temperature. Young's moduli shear moduli and Poisson coefficients, can be determined from the components of the elasticity tensor.

This International Standard applies to ceramic matrix composites with a continuous fibre reinforcement: unidirectional (1D), bidirectional (2D), and tridirectional ($\times D$, with $2 < \times \leq 3$) which have at least orthotropic symmetry, and whose material symmetry axes are known.

This method is applicable only when the ultrasonic wavelength used is larger than the thickness of the representative elementary volume, thus imposing an upper limit to the frequency range of the transducers used.

NOTE Properties obtained by this method might not be comparable with moduli obtained by EN 658-1, EN 658-2 and EN 12289. (Check for ISO EQUIVALENT)

3 Terms definitions and symbols

For the purposes of this document, the terms and definitions given in CEN/TR 13233:2007 and the following apply.

3.1 stress-strain relations for orthotropic material

elastic anisotropic behaviour of a solid homogeneous body described by the elasticity tensor of fourth order C_{ijkl} , represented in the contracted notation by a symmetrical square matrix (6×6)

Note 1 to entry: If the material has at least orthotropic symmetry, its elastic behaviour is fully characterized by nine independent stiffness components C_{ij} , of the stiffness matrix (C_{ij}), which relates stresses to strains, or equivalently by nine independent compliance components S_{ij} of the compliance matrix (S_{ij}), which relates strains to stresses. The stiffness and compliance matrices are the inverse of each other.

If the reference coordinate system is chosen along the axes of symmetry, the stiffness matrix C_{ij} and the compliance matrix S_{ij} can be written as follows:

$$\begin{bmatrix} \sigma_1 \\ \sigma_2 \\ \sigma_3 \\ \sigma_4 \\ \sigma_5 \\ \sigma_6 \end{bmatrix} = \begin{bmatrix} C_{11} & C_{12} & C_{13} & 0 & 0 & 0 \\ C_{12} & C_{22} & C_{23} & 0 & 0 & 0 \\ C_{13} & C_{23} & C_{33} & 0 & 0 & 0 \\ 0 & 0 & 0 & C_{44} & 0 & 0 \\ 0 & 0 & 0 & 0 & C_{55} & 0 \\ 0 & 0 & 0 & 0 & 0 & C_{66} \end{bmatrix} \begin{bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \varepsilon_3 \\ \varepsilon_4 \\ \varepsilon_5 \\ \varepsilon_6 \end{bmatrix}$$

$$\begin{bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \varepsilon_3 \\ \varepsilon_4 \\ \varepsilon_5 \\ \varepsilon_6 \end{bmatrix} = \begin{bmatrix} S_{11} & S_{12} & S_{13} & 0 & 0 & 0 \\ S_{12} & S_{22} & S_{23} & 0 & 0 & 0 \\ S_{13} & S_{23} & S_{33} & 0 & 0 & 0 \\ 0 & 0 & 0 & S_{44} & 0 & 0 \\ 0 & 0 & 0 & 0 & S_{55} & 0 \\ 0 & 0 & 0 & 0 & 0 & S_{66} \end{bmatrix} \begin{bmatrix} \sigma_1 \\ \sigma_2 \\ \sigma_3 \\ \sigma_4 \\ \sigma_5 \\ \sigma_6 \end{bmatrix}$$

Note 2 to entry: For symmetries of higher level than the orthotropic symmetry, the C_{ij} and S_{ij} matrices have the same form as here above. Only the number of independent components reduces.

3.2 engineering constants

compliance matrix components of an orthotropic material which are in terms of engineering constants:

$$[S_{ij}] = \begin{bmatrix} 1/E_{11} & -\nu_{21}/E_{22} & -\nu_{31}/E_{33} & 0 & 0 & 0 \\ -\nu_{12}/E_{11} & 1/E_{22} & -\nu_{32}/E_{33} & 0 & 0 & 0 \\ -\nu_{13}/E_{11} & -\nu_{23}/E_{22} & 1/E_{33} & 0 & 0 & 0 \\ 0 & 0 & 0 & 1/G_{23} & 0 & 0 \\ 0 & 0 & 0 & 0 & 1/G_{13} & 0 \\ 0 & 0 & 0 & 0 & 0 & 1/G_{12} \end{bmatrix}$$

where

- E_{11}, E_{22} and E_{33} are the elastic moduli in directions 1, 2 and 3 respectively;
- G_{12}, G_{13} and G_{23} are the shear moduli in the corresponding planes;
- $\nu_{12}, \nu_{13}, \nu_{23}$ are the respective Poisson coefficients

3.3**angle of incidence** θ_i

angle between the direction 3 normal to the test specimen front face and the direction n_i of the incident wave (see [Figure 1](#) and [Figure 2](#))

3.4**refracted angle** θ_r

angle between the direction 3 normal to the test specimen front face and the direction n of propagation of the wave inside the test specimen (see [Figure 1](#) and [Figure 2](#))

3.5**azimuthal angle** ψ

angle between the plane of incidence ($3, n_i$) and plane $(2, 3)$ where n_i corresponds to the vector oriented along the incident plane wave and direction 2 corresponds to one of the axes of symmetry of the material (see [Figure 1](#))

Figure 1 — Definition of the angles

Figure 2 — Propagation in the plane of incidence

3.6
first critical angle

θ_c
angle of incidence θ_i that provides an angle of refraction of 90-degrees of the quasi longitudinal wave angle

3.7
unit vector

n
unit vector oriented along the propagation direction of the incident plane wave inside the specimen, with its components n_k ($k = 1, 2, 3$) (see [Figure 1](#) and [Figure 2](#)): $n_1 = \sin\theta_r \sin\psi$, $n_2 = \sin\theta_r \cos\psi$, $n_3 = \cos\theta_r$

3.8
propagation velocity

$V(n)$
phase velocity of a plane wave inside the specimen in dependence on unit vector n (i.e. in dependence on ψ and θ_r)

Note 1 to entry: V_0 is the propagation velocity in the coupling fluid.

3.9
delay

$\delta t(n)$
difference between the flight time of the wave when the test specimen is in place and the flight time of the wave in the coupling fluid with the test specimen removed under the same configuration of the transducers in dependence on unit vector n

3.10
bulk density

ρ
bulk density of the specimen without porosity

4 Principle

The determination of the elastic properties consists of calculating the coefficients of the propagation equation of an elastic plane wave, from a set of properly chosen velocity measurements along known directions.

A thin specimen with plane parallel faces is immersed in an acoustically coupling fluid (e.g. water): see [Figure 3](#). The specimen is placed between an emitter (E) and a receiver (R), which are rigidly connected to each other and have two rotational degrees of freedom. Using appropriate signal processing, the propagation velocities of each wave in the specimen are calculated.

**Key**

- 1 rotation drive
- 2 test specimen
- 3 pulse generator
- 4 digital oscilloscope
- 5 micro-computer

Figure 3 — Ultrasonic test assembly

Depending on the angle of incidence, the wave created by the pulse sent by the emitter E is refracted within the material in one (a quasi longitudinal wave QL , or a quasi transverse wave QT), two ($QL+QT$ or two quasi transverse waves QT_1, QT_2) or three bulk waves ($QL+QT_1+QT_2$) that propagate in the solid at different velocities and in different directions.

The receiver R collects one, two or three pulses, corresponding to each of these waves.

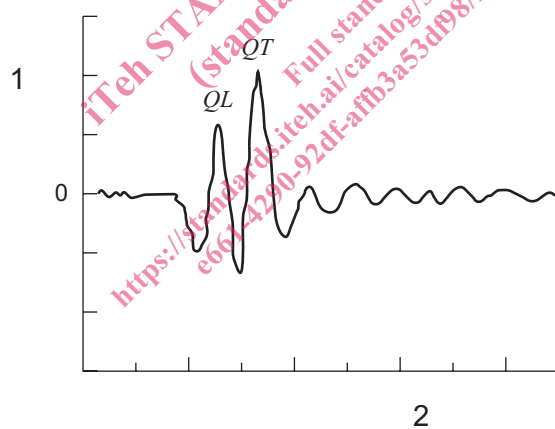

The difference between the propagation time of each of the waves and the propagation time of the emitted pulse in the coupling fluid without the specimen is measured. The evaluation procedure is based on the measurement of the time of flight of the quasi-longitudinal and one or both quasi-transverse waves, and is only valid when the QL and the QT waves are appropriately separated (see [Figure 4](#)).

Key

- 1 amplitude
- 2 incidence angle

a) Amplitude of the QL and QT waves as a function of the incidence angle with overlapping in the region of θ_c

Key

- 1 amplitude
- 2 time

b) Temporal waveform of the QL and QT waves at an incidence angle θ_i close to the critical angle θ_c . Both QL and QT waves are present and can be distinguished in the positive domain but are slightly overlapping in the negative domain

Figure 4 — Example of partial Overlapping of QL and QT waves at an incidence angle θ_i

From the propagation velocities the components of the elasticity tensor are obtained through a least square regression analysis which minimises the residuals of the wave propagation equations.

Young's moduli, shear moduli and Poisson coefficients are determined from these components.
