Foreword

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialized system for worldwide standardization. National bodies that are members of ISO or IEC participate in the development of International Standards through technical committees established by the respective organization to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organizations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work. In the field of information technology, ISO and IEC have established a joint technical committee, ISO/IEC JTC 1.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular the different approval criteria needed for the different types of document should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO and IEC shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see www.iso.org/patents).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation on the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the WTO principles in the Technical Barriers to Trade (TBT) see the following URL: Foreword - Supplementary information

The committee responsible for this document is ISO/IEC JTC 1, *Information technology*, SC 29, *Coding of audio, picture, multimedia and hypermedia information*.

This third edition cancels and replaces the second edition (ISO/IEC 23001-4:2011), which has been technically revised.

ISO/IEC 23001 consists of the following parts, under the general title *Information technology — MPEG systems technologies*:

— *Part 1: Binary MPEG format for XML*

— *Part 2: Fragment request units*

— *Part 3: XML IPMP messages*

— *Part 4: Codec configuration representation*

— *Part 5: Bitstream Syntax Description Language (BSDL)*

— *Part 7: Common encryption in ISO base media file format files*

— *Part 8: Coding-independent code points*

— *Part 9: Common encryption of MPEG-2 transport streams*

Introduction

This part of ISO/IEC 23001 defines the methods capable of describing codec configurations in the so-called reconfigurable video coding (RVC) framework. The objective of RVC is to offer a framework that is capable of configuring and specifying video codecs as a collection of “higher level” modules by using video coding tools. The video coding tools are defined in video tool library. Part 4 of ISO/IEC 23002 defines the MPEG video tool library. The RVC framework principle could also support non-MPEG tool libraries, provided that their developers have taken care to obey the appropriate rules of operation.

For the purpose of framework deployment, an appropriate description is needed to describe configurations of decoders composed of or instantiated from a subset of video tools from either one or more libraries. As illustrated in Figure 1, the configuration information consists of:

— bitstream syntax description, and

— network of functional units (FUs) description (also referred to as the decoder configuration)

that together constitute the entire decoder description (DD).

Bitstreams of existing MPEG standards are specified by specific syntax structures and decoders are composed of various coding tools. Therefore, RVC includes support for bitstream syntax descriptions as well as video coding tools. As depicted in Figure 1, a typical RVC decoder requires two types of information, namely the decoder description and the encoded media (e.g. video bitstreams) data.

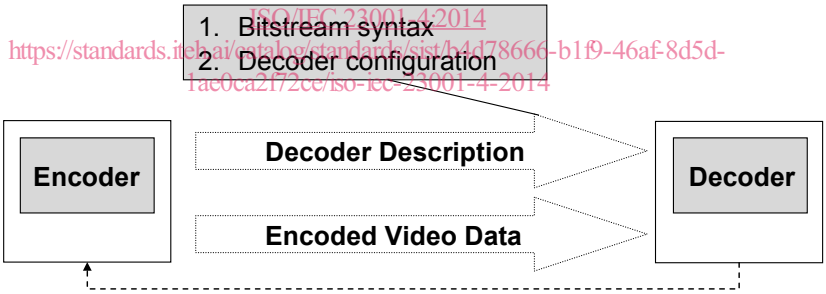

Figure 1 — Conceptual diagram of RVC

Figure 2 illustrates a more detailed description of the RVC decoder.

A more detailed description of the RVC decoder is shown in Figure 2. As shown in Figure 2, the decoder description is required for the configuration of a RVC decoder. The Bitstream Syntax Description (BSD) and FU Network Description (FND) (which compose the Decoder Description) are used to configure or compose an abstract decoder model (ADM) which is instantiated through the selection of FUs from tool libraries optionally with proper parameter assignment. Such an ADM constitutes the behavioral reference model used in setting up a decoding solution under the RVC framework. The process of yielding a decoding solution may vary depending on the technologies used for the desired implementations. Examples of the instantiation of an abstract decoder model and generation of proprietary decoding solutions are given in Annex I.

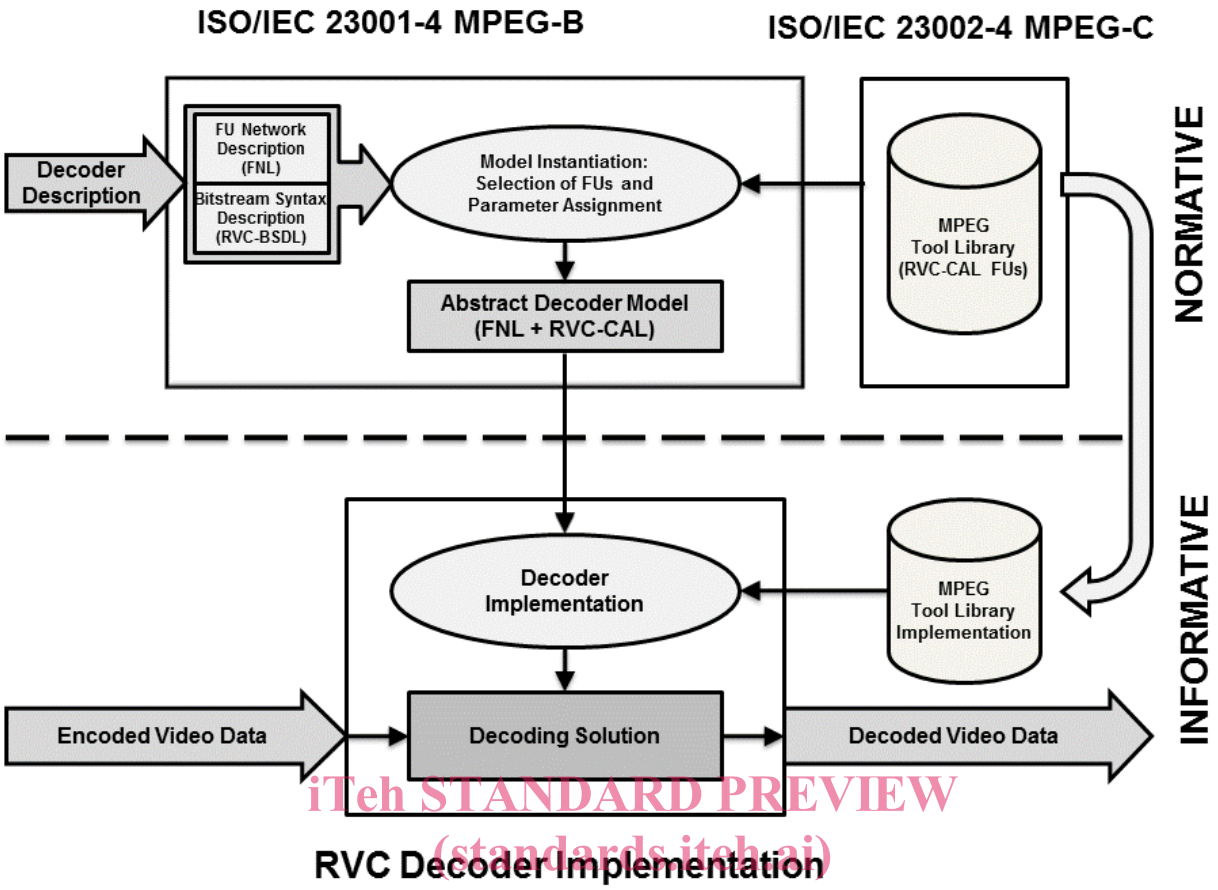

Figure 2 — Graphical representation of the instantiation process or decoder composition mechanism for the RVC normative ADM and for the non-normative proprietary compliant decoder implementation

Within the RVC framework, the decoder description describes a particular decoder configuration and consists of the FND and the BSD. The FND describes the connectivity of the network of FUs used to form a decoder whereas the parsing process for the bitstream syntax is implicitly described by the BSD. These two descriptions are specified using two standard XML-based languages or dialects:

— Functional Unit Network Language (FNL) is a language that describes the FND, known also as “network of FUs”. The FNL specified normatively within the scope of the RVC framework is provided in this part of ISO/IEC 23001;

— Bitstream Syntax Description Language (BSDL), standardized in ISO/IEC 23001-5 (MPEG-B Part 5), describes the bitstream syntax and the parsing rules. A pertinent subset of this BSDL named RVC-BSDL is defined within the scope of the current RVC framework. This RVC-BSDL also includes possibilities for further extensions, which are necessary to provide complete description of video bitstreams. RVC-BSDL specified normatively within the scope of the RVC framework is provided in this part of ISO/IEC 23001.

The decoder configuration specified using FNL, together with the specification of the bitstream syntax using RVC-BSDL fully specifies the ADM and provides an “executable” model of the RVC decoder description.

The instantiated ADM includes the information about the selected FUs and how they should be connected. As already mentioned, the FND with the network connection information is expressed by using FNL. Furthermore, the RVC framework specifies and uses a dataflow-oriented language called RVC-CAL for describing FUs' behavior. The normative specification of RVC-CAL is provided in this part of ISO/IEC 23001. The ADM is the behavioral model that should be referred to in order to implement any RVC conformant decoder. Any RVC compliant decoding solution/implementation can be achieved by using proprietary non-normative tools and mechanisms that yield decoders that behave equivalent to the RVC ADM.

The decoder description, the MPEG video tool library, and the associated instantiation of an ADM are normative. More precisely, the ADM is intended to be normative in terms of a behavioral model. In other words what is normative is the input/output behavior of the complete ADM as well as the input/output behavior of all the FUs that are included in the ADM.

Information technology — MPEG systems technologies —

Part 4:
Codec configuration representation

1 Scope

This part of ISO/IEC 23001 defines the methods and general principles capable of describing codec configurations in the so-called reconfigurable video coding (RVC) framework. It primarily addresses reconfigurable video aspects and will only focus on the description of representation for video codec configurations within the RVC framework.

Within the scope of the RVC framework, two languages, namely FNL and RVC-BSDL, are specified normatively. FNL is a language that describes the FND, also known as “network of FUs”. RVC-BSDL is a pertinent subset of BSDL defined in ISO/IEC 23001-5. This RVC-BSDL also includes possibilities for further extensions, which are necessary to provide complete description of video bitstreams.

2 Normative references

The following documents, in whole or in part, are normatively referenced in this document and are indispensable for its application. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

3.1
ADM
abstract decoder model
conceptual model of the instantiation of the **functional units** (3.8) from the **video tool library** (3.16) and their connection according to the **FU network description** (3.9)

3.2
BSD
bitstream syntax description
description containing the bitstream syntax, its implicit parsing rules, and possibly tables [e.g. VLD tables if not already existing in the **reconfigurable video coding** (3.13) **video tool library**] to define the parser **functional unit** (3.8)

NOTE The BSD is expressed using **reconfigurable video coding-bitstream syntax description language** (3.14).

3.3
BSDL
bitstream syntax description language
description of the bitstream syntax and the parsing rules

NOTE Bitstream syntax description language (BSDL) is standardized by ISO/IEC 23001-5.

3.4
connection
link from an output port to an input port of a **functional unit** (3.8) that enables token exchange between FUs

3.5
decoder configuration
conceptual configuration of a decoding solution

NOTE 1 Using the **MPEG video tool library** (3.12), decoder configuration can be designed as one of the following cases.

— A decoding solution of an existing MPEG standard at a specific profile and level.

— A new decoding solution built from tools of an existing MPEG standard.

— A new decoding solution built from tools of an existing MPEG standard and some new MPEG tools included in the MPEG video tool library.

— A new decoding solution that is composed of new MPEG tools included in the MPEG video tool library.

NOTE 2 In summary, an RVC decoder description essentially consists of a list of **functional units** (3.8) and of the specification of the FU connections [**FU network description** (3.9) expressed in **FU network language** (3.10)] plus the implicit specification of the parser in terms of **bitstream syntax description** (3.2) [BSD expressed in **reconfigurable video coding-bitstream syntax description language** (3.14)]. In order to be a complete behavioral model [i.e. **abstract decoder model** (3.1)] an RVC **decoder description** (3.6) needs to make reference to the behavior of each FU that is provided in terms of I/O behavior by the **MPEG video tool library** (3.12) specified in ISO/IEC 23002-4.

3.6
DD
decoder description
description of a particular decoder configuration, which consists of two parts: **FU network description** (3.9) and **bitstream syntax description** (3.2)

3.7
decoding solution
implementation of the **abstract decoder model** (3.1)

3.8
FU
functional unit
modular tool which consists of a processing unit characterized by the input/output behavior

3.9
FND
FU network description
FU (3.8) connections used in forming a decoder which are modeled using **FU network language** (3.10)

3.10
FNL
FU network language
language that describes the **FU network description** (3.9), known also as a “network of FUs”

3.11
model instantiation
building of the **abstract decoder model** (3.1) from the **decoder description** (3.6) [consisting of the **bitstream syntax description** (3.2) and the **FU network description** (3.9)] and from **functional units** (3.8) from the **video tool library** (3.16)

NOTE During the model instantiation, the parser FU is reconfigured according to the BSD or loaded from VTL.

3.12
MPEG video tool library
MPEG VTL
video tool library (3.16) that contains **functional units** (3.8) defined by MPEG, that is, drawn from existing MPEG International Standards

3.13
RVC
reconfigurable video coding
framework defined by MPEG to promote coding standards at tool-level while maintaining interoperability between solutions from different implementers

3.14
RVC-BSDL
reconfigurable video coding-bitstream syntax description language
pertinent subset of **bitstream syntax description language** (3.3), which is defined within the scope of the current **reconfigurable video coding** (3.13) framework

3.15
token
data entity exchanged between input and output among **functional units** (3.8)

3.16
VTL
video tool library
collection of **functional units** (3.8)

4 Functional unit network description

4.1 Introduction

The FUs in MPEG RVC are specified by:

- The textual description in ISO/IEC 23002-4.
- The RVC-CAL reference software. The RVC-CAL language is formally specified in Annex D.

The Functional Unit Network Language (FNL) is formally specified in this Clause and is used to describe networks of FUs. FNL is derived from Extensible Markup Language (XML) which was in turn derived from SGML (ISO 8879). The ADM consists of a number of FUs with input and output ports, and the connections between those ports. In addition, the ADM may have input and output ports, which may be connected to the ports of FUs or to each other.

A decoder can be described as a network of a number of FUs or even only one FU (e.g. Figure 3).

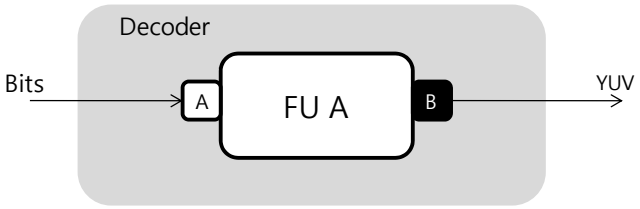

Figure 3 — FU network of one FU

A network of FUs is described in FND. An FND includes the list of the selected FUs to form the decoder and the three types of connections that are connections between FUs (type A), connections between decoder inputs and FU inputs (type B), and connections between FU outputs and decoder outputs (type C), which are illustrated in Figure 4.

The list of the selected FUs (Figure 4) is described in FND according to the following table. When selecting FUs from VTL, the IDs and names of FUs defined in ISO/IEC 23002-4 shall be used in the FND. The parameter assignments in the listed FUs are supported in the FND, but optional.

```
<Instance  id = "FU A">
     <Class name = "Algo_Example1" />
</Instance>
<Instance id = "FU B">
     <Class name = "Algo Example2" />
</Instance>
```

The connections (type A, type B, and type C shown in Figure 4) are described in FND as shown in the following table.

Type A	`<Connection src = "FU A" src-port = "B" dst = "FU B" dst-port = "D" />` `<Connection src = "FU A" src-port = "C" dst = "FU B" dst-port = "E" />`
Type B	`<input src = "FU A" src-port = "A" />`
Type C	`<output src = "FU B" src-port = "F" />`

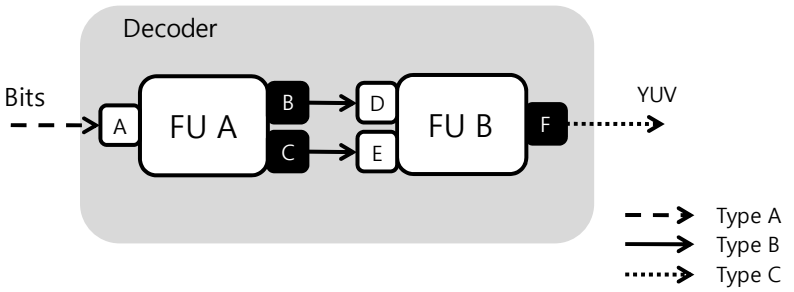

Figure 4 — Three types of connections in an FU network

Another example of FU networks with four FUs is illustrated in Figure 5. The textual description of Figure 5 in FND is described as follows.

```
<XDF name="Decoder">
<Instance id = "Syntax parser">
    <Class name = "syntax parser">
</Instance>
<Instance id = "FU A">
    <Class name = "Algo ExamFU A">
</Instance>
<Instance id = "FU B">
    <Class name = "Algo_ExamFU_B">
</Instance>
```

```
<Instance id = "FU C">
    <Class name = "Algo_ExamFU_C">
</Instance>
<Input src = "Syntax Parser" src-port = "A" />
<Output src = "FU C" src-port = "R" />
<Connection src = "Syntax Parser" src-port = "B" dst = "FU A" dst-port = "E" />
<Connection src = "Syntax Parser" src-port = "C" dst = "FU A" dst-port = "F" />
<Connection src = "Syntax Parser" src-port = "D" dst = "FU B" dst-port = "K" />
<Connection src = "FU A" src-port = "H" dst = "FU C" dst-port = "O" />
<Connection src = "FU B" src-port = "L" dst = "FU C" dst-port = "P" />
<Connection src = "FU B" src-port = "M" dst = "FU C" dst-port = "Q" />
</XDF>
```

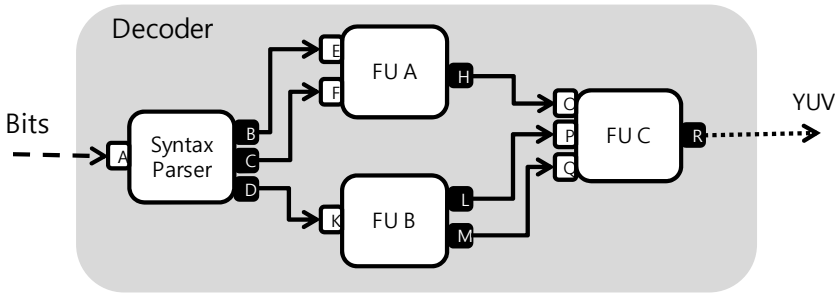

Figure 5 — Another example of FU networks

4.2 The specification of an FU network

The XML structures with names of elements, such as Decl, Network, Package, Expr, etc. are described in the specification of FNL in Annex A. In addition, attributes that direct an individual element's features are also introduced there. Attribute names will be prefixed with "@". For instance common attribute names are @id, @name, or @kind. In cases where an element name may be qualified by the value of an attribute, square brackets are used. For instance, in order to express the notion of an Expr element whose @kind attribute is the string "literal", Expr[@kind="literal"] is written.

By using the RVC-CAL model, FNL also allows FU networks and individual FUs to be parameterized. In particular, it is possible to pass bounded values for specific parameters into FU and FU networks. These values are represented by Expr and Decl syntax. Expr and Decl are the syntactical constructs describing a computation, which may, itself, be dependent upon the values of parameters which are either global or local variables.

5 Bitstream syntax description

The MPEG video tool library contains FUs that specify MPEG decoding tools. A new decoder configuration implies new bitstream syntax. The description of the bitstream syntax in RVC is provided using BSDL as specified in ISO/IEC 23001-5 and BSDL schema. However, to facilitate the developments of synthesis tools that are able to generate parsers directly from a BSD (i.e. a BSDL schema), the RVC framework standardizes a version of BSDL called RVC-BSDL specified by including new RVC specific extensions and usage restrictions of standard BSDL in ISO/IEC 23001-5. Such extensions and restrictions versus the MPEG standard BSDL are defined in Annex C of this document. RVC-BSDL contains all information necessary to parse any bitstream compliant with such syntax. The procedure to instantiate the parser capable of parsing and decoding any bitstream compliant with the syntax specified by the RVC-BSDL schema is not normative. Examples of such non-normative procedures are provided in Annex I.

6 Model instantiation

This Clause describes the model instantiation process which consists of the selection of Functional Units (FUs) from the video tool library and instantiation of the FUs with the proper parameter assignments. The instantiation process requires the following information:

- The video tool library
- The FU network description
- The bitstream syntax description

The instantiation process consists of attaching the source code corresponding to the FUs identified in the FND in order to build a complete model that can be simulated. The video tool library is a library of source code of all FUs standardized in ISO/IEC 23002-4. The FND contains only the references (names of the FUs) to the pieces of code in the VTL. The process outputs the ADM. Figure 6 illustrates the model instantiation process.

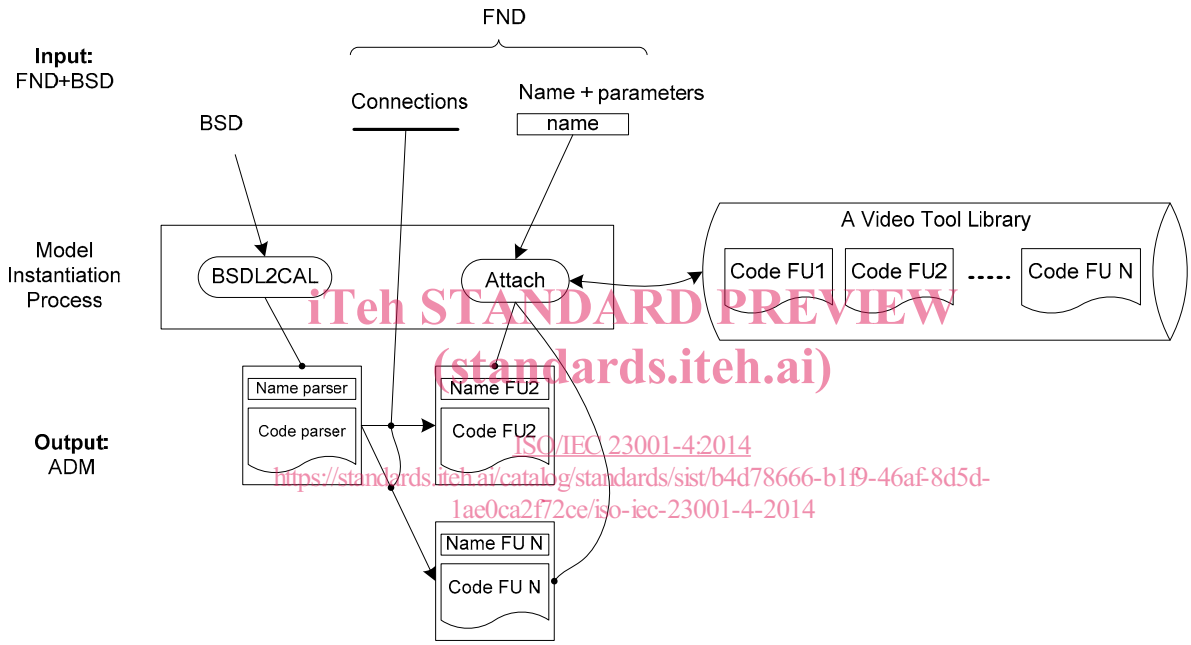

Figure 6 — Description of the model instantiation process

The FU Network Description (FND) provides the structure of the decoder by giving the names of the FUs composing the decoder and their respective connections among them. The name of the instance of the FU in the ADM is contained in the tag `<instance id="…">`. The tag `<class name="…">` indicates the name of the FU (in the video tool library) from which the FU of the ADM must be instantiated. The tag `<parameter>` provides the values of the parameters, which must be used for the instantiation of the FU in the ADM.

The Bitstream Syntax Description (BSD) provides the structure of the bitstream. The parser is generated automatically from the BSD. Informative examples are provided in Annex I for building the parser. The syntax parser FU of the ADM might use other FUs to parse the bitstream. Thus, a clear link between identifiers inside the BSD and the FND must be established. The tag `<rvc port="…">` indicates the name of the instance of the FU into the ADM to which this element of syntax is sent.

Annex A
(normative)

Functional unit network description

A.1 Elements of a functional unit network

XDF — An FU network is identified by the root element called XDF that marks the beginning and end of the XML description of the network.

- optional attribute: @name, the name of the network. @version, the version number of the current network. Assumed to be “1.0” if absent.
- optional children: Package, Decl, Port, Instance, Connection.

```
<XDF name="mpeg4SP">
   ...
</XDF>
```

Package — This element contains a structured representation of a qualified identifier (QID) (i.e. a list of identifiers that are used to specify a locus in a hierarchical namespace). That QID provides the context for the @name attributed of the enclosing Network element: that name is intended to be valid within the specified namespace, or package.

- required child: QID, the qualified identifier.

```
<Package>
   <QID>
      <ID id="mpeg4"/>
   </QID>
</Package>
```

Decl[@kind="Param"] — Represents the declaration of a parameter of the network.

- required attribute: @name, the name of the parameter.
- optional child: Type, the declared type of the parameter.

```
<Decl kind="Param" name="FOURMV"/>
```

Decl[@kind="Var"] — This element represents a variable declaration. Variables are used within expressions to compute parameter values for actors instantiated within the network and within expressions used to compute the values of other variables.

- required attribute: @name, containing the name of the declared variable.
- required child: Expr, representing the expression defining the value of this variable, possibly referring the values of other variables and parameters.
- optional child: Type, the declared type of the variable.

```
<Decl kind="Variable" name="MOTION">
      <Expr kind="Literal" literal-kind="Integer" value="8"/>
</Decl>
```
