## Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see [www.iso.org/directives](http://www.iso.org/directives)).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see [www.iso.org/patents](http://www.iso.org/patents)).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT) see [www.iso.org/iso/foreword.html](http://www.iso.org/iso/foreword.html).

This document was prepared by Technical Committee ISO/TC 112, *Vacuum technology*.

A list of all parts in the ISO 21360 series can be found on the ISO website.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at [www.iso.org/members.html](http://www.iso.org/members.html).

## Introduction

This document specifies methods for measuring the performance data of turbomolecular vacuum pumps. This document complements ISO 21360-1, which provides a general description of the measurement of performance data of vacuum pumps.

The methods described here are well known from existing national and international standards. The aim in drafting this document was to collect together suitable methods for the measurement of performance data of turbomolecular vacuum pumps. This document takes precedence in the event of a conflict with ISO 21360-1.

# Vacuum technology — Standard methods for measuring vacuum-pump performance —

## Part 4: Turbomolecular vacuum pumps

### 1 Scope

This document, in conjunction with ISO 21360-1, specifies methods for the measurement of performance characteristics of turbomolecular vacuum pumps. It is applicable to all sizes and all types of turbomolecular vacuum pumps, including those

- with mechanical or magnetic bearings;
- with or without an additional drag stage(s) or other pumping stages on the shaft;
- with one or more inlet ports.

Since turbomolecular vacuum pumps are backed by primary pumps, their performance cannot be completely defined by the volume flow rate curve. Also, the driving device and the backing pressure of the turbomolecular vacuum pump is important to the performance.

The following completes the performance characteristics:

- information about throughputs and backing pressure of the turbomolecular vacuum pump;
- the compression ratio curve (compression ratio vs backing pressure of turbomolecular vacuum pump).

### 2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO 21360-1:2012, *Vacuum technology — Standard methods for measuring vacuum-pump performance — Part 1: General description*

### 3 Terms and definitions

For the purposes of this document, the terms and definitions given in ISO 21360-1 and the following apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

- ISO Online browsing platform: available at <https://www.iso.org/obp>
- IEC Electropedia: available at <http://www.electropedia.org/>

### 3.1 critical backing pressure

$p_c$   
maximum backing pressure  $p_3$  on the outlet that the vacuum pump and the driving device can withstand for continuous operation without being damaged or overloaded while the pump still has a compression ratio  $p_3/p_1 > 10$  and the purge gas flow is off

Note 1 to entry:  $p_1$  is the (high) vacuum pressure on inlet. The rotational speed of the turbomolecular vacuum pump can be reduced at this working point. The value of  $p_c$  depends on the rotational speed and the type of gas, therefore both shall be named together with the value of  $p_c$ .

Note 2 to entry: Measurement with purge gas leads to different results (during pumping light gases at the inlet the use of heavy purge gas will influence the performance regarding critical backing pressure  $p_c$ ). Therefore, the purge gas flow has to be zero.

### 3.2 maximum throughput

$Q_{\max}$   
highest gas load that can be pumped continuously without damage or destruction of the pump

Note 1 to entry: Given in pascal litres per second (Pa l/s), millibar litres per second (mbar l/s) or standard cubic centimetres per minute (scm).

Note 2 to entry: The limiting parameter depends on the design of the pump. In most cases it will be given as a maximum temperature at defined locations. The value of  $Q_{\max}$  depends on, for example, the gas pumped, the backing pump used, the rotational speed and the conditions of cooling. If the  $Q_{\max}$  is stated in the units Pa l/s or mbar l/s, then the test dome temperature shall also be documented, because this value depends on the gas temperature. This is not the case if the  $Q_{\max}$  value is stated in the unit scm.

### 3.3 volume flow rate

$q_v$   
<https://standards.iteh.ai/catalog/standards/sist/c23eee13-0725-4547-b436-c513d95c578f/iso-21360-4-2018>

$$q_v = \frac{dV}{dt} \quad (1)$$

where

$V$  is the volume;

$t$  is time.

EXAMPLE In the context of the ISO 21360 series, the volume flow rate is the volume of gas per unit time which, under ideal conditions, flows from the test dome through the pump inlet.

Note 1 to entry: For practical reasons, the volume flow rate of a given pump and for a given gas is conventionally considered to be equal to the quotient of the throughput of this gas and of the equilibrium pressure at a given location. The volume flow rate is expressed in cubic metres per hour or litres per second.

Note 2 to entry: The term “pumping speed” and symbol “ $S$ ” are often used instead of “volume flow rate”.

[SOURCE: ISO 21360-1:2012, 3.1]

### 3.4 ultimate pressure

value towards which the pressure in the test dome approaches asymptotically

Note 1 to entry: This ultimate pressure is always lower than the base pressure  $p_{b1}$ .

Note 2 to entry: It is the lowest pressure obtainable with the pump.

Note 3 to entry: It is recommended that ultimate pressure values are not given in the manufacturer's specification. Therefore, no procedure to measure the ultimate pressure is given in this document. However, if the manufacturer lists the ultimate pressure, the operating conditions and measurement time durations under which the measurement is made should be stated.

### 3.5 base pressure turbomolecular pump

$p_{b1}$   
pressure obtained in the dome 48 h after the bake-out procedure

Note 1 to entry: That is the conditioning of the vacuum pump and the test system without any test gas (see 5.6).

### 3.6 effective compression ratio

$K_{\text{eff}}$   
ratio of the backing pressure  $p_3$  to the inlet pressure  $p_1$  of the turbomolecular vacuum pump

$$K_{\text{eff}} = \frac{p_3}{p_1} \quad (2)$$

### 3.7 compression ratio

$K_0$   
maximum compression ratio without gas load through the turbomolecular vacuum pump, wherein  $p_{b3}$  is the base pressure of the backing pump and  $p_{b1}$  is the base pressure of the turbomolecular vacuum pump

$$K_0 = \frac{p_3 - p_{b3}}{p_1 - p_{b1}} \quad (3)$$

## 4 Symbols and abbreviated terms

Symbol	Designation	Unit
$K_{\text{eff}}$	compression ratio of vacuum pump	—
$K_0$	maximum compression ratio of vacuum pump at zero throughput	—
$p_{b1}$	base pressure turbomolecular pump	Pa (or mbar)
$p_{b3}$	base pressure of backing pump	Pa (or mbar)
$p_1$	(high) vacuum pressure on inlet	Pa (or mbar)
$p_3$	vacuum pressure in backing line	Pa (or mbar)
$p_c$	critical backing pressure	Pa (or mbar)
$Q$	throughput of vacuum pump	Pa l/s (or mbar l/s) or sccm
$Q_{\text{max}}$	maximum throughput	Pa l/s (or mbar l/s) or sccm
$q_V$	volume flow rate	l/s
$q_{V0}$	volume flow rate at $K_{\text{eff}} = 1$	l/s
