ICS 93.080.20

English Version

Bituminous mixtures - Test methods - Part 48: Interlayer Bonding

Mélanges bitumineux - Méthodes d'essai - Partie 48:
Lien de couches

Asphalt - Prüfverfahren - Teil 48: Schichtenverbund

This draft European Standard is submitted to CEN members for enquiry. It has been drawn up by the Technical Committee CEN/TC 227.

If this draft becomes a European Standard, CEN members are bound to comply with the CEN/CENELEC Internal Regulations which stipulate the conditions for giving this European Standard the status of a national standard without any alteration.

This draft European Standard was established by CEN in three official versions (English, French, German). A version in any other language made by translation under the responsibility of a CEN member into its own language and notified to the CEN-CENELEC Management Centre has the same status as the official versions.

CEN members are the national standards bodies of Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Republic of North Macedonia, Romania, Serbia, Slovakia, Slovenia, Spain, Sweden, Switzerland, Turkey and United Kingdom.

<https://standards.iteh.ai/catalog/standards/sist/86c575da-ed48-43df-b199->

Recipients of this draft are invited to submit, with their comments, notification of any relevant patent rights of which they are aware and to provide supporting documentation.

Warning : This document is not a European Standard. It is distributed for review and comments. It is subject to change without notice and shall not be referred to as a European Standard.

prEN 12697-48:2019 (E)

European foreword

This document (prEN 12697-48:2019) has been prepared by Technical Committee CEN/TC 227 “Road materials”, the secretariat of which is held by BSI.

This document is currently submitted to the CEN Enquiry.

A list of all parts in the EN 12697 series can be found on the CEN website.

iTeh STANDARD PREVIEW (standards.iteh.ai)

[oSIST prEN 12697-48:2020](https://standards.iteh.ai/catalog/standards/sist/86c575da-ed48-43df-b199-aeb70c42fc7f/osist-pren-12697-48-2020)

<https://standards.iteh.ai/catalog/standards/sist/86c575da-ed48-43df-b199-aeb70c42fc7f/osist-pren-12697-48-2020>

1 Scope

This document specifies test methods for determining the bond strength between an asphalt layer and other newly constructed construction layers or existing substrates in road or airfield pavements. The tests can also be applied on laboratory prepared interlayers.

The normative tests described in this document are:

- Torque Bond Test (TBT), generally applicable to any layer thicknesses;
- Shear Bond Test (SBT), generally applicable to layer thicknesses ≥ 15 mm;
- Tensile Adhesion Test (TAT), generally applicable to layer thicknesses < 15 mm;

NOTE 1 Further non normative test methods are described in informative annexes:

- Annex A (informative) - Compressed shear bond test (CSBT)
- Annex B (informative) - Cyclic compressed shear bond test (CCSBT)
- Annex C (informative) - Alternative Shear bond test (ASBT)
- Annex D (informative) - Layer Adhesion Measuring Instrument (LAMI)

2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

3 Terms and Definitions

For the purposes of this document, the following terms and definitions apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

- IEC Electropedia: available at <http://www.electropedia.org/>
- ISO Online browsing platform: available at <http://www.iso.org/obp>

3.1

peak shear stress of the interface

$\tau_{\text{SBT,max}}$

maximum value of shear stress [MPa], determined as the maximum force F divided by the initial cross sectional area A , of a specimen when tested as described in this document

prEN 12697-48:2019 (E)**3.2
displacement at peak shear stress** **$\delta_{\text{SBT,max}}$**

displacement at the maximum value of shear stress, of a specimen when tested as described in this document

**3.3
shear stiffness modulus** **$k_{\text{SBT,max}}$**

slope of the shear stress versus displacement - graph, determined from the linear part of the graph

**3.4
effective cross sectional area**

value of the effective contact area between the two layers of the specimen

Note 1 to entry: This area can be express as a function of the relative displacement of the two portions of the specimen as shown in Figure A.3.

**3.5
dilatancy**

ratio between the difference of the last two current recorded values of the vertical and the horizontal displacement [$d = (\eta_i - \eta_{i-1}) / (\delta_i - \delta_{i-1})$], of a specimen when tested as described in Annex A

**3.9
normal stress**

ratio between the normal load and the effective cross sectional area, of a specimen when tested as described in Annex A

iTeh STANDARD PREVIEW
(standards.iteh.ai)

[oSIST prEN 12697-48:2020](https://standards.iteh.ai/catalog/standards/sist/86c575da-cd48-43df-b199-aeb70c42fc7f/osist-pren-12697-48-2020)

**3.10
critical condition**

<https://standards.iteh.ai/catalog/standards/sist/86c575da-cd48-43df-b199-aeb70c42fc7f/osist-pren-12697-48-2020>

shearing of the interface in residual (pure friction) condition at constant volume, of a specimen when tested as described in Annex A

4 Principle**4.1 General**

The described test methods simulate different loading conditions and are applicable on different bonds between road construction layers. The methods give different results because they measure different failure modes.

4.2 Torque Bond Test (TBT)

The torque bond test assesses the resistance to horizontal shear stress:

- The torque bond test is suitable for testing the bond strength between road layers in laboratory and *in situ*;
- The torque bond test assesses the resistance to the stresses generated primarily by traffic accelerating or braking, but also by different thermal movements when the layers are of different materials;
- The torque bond test can be carried out immediately after laying;
- The torque bond test can be applied to assess the capability of bond coats or tack coats.

When the thickness of the top layer above the interlayer assessed is less than 15 mm, the torque bond test can be applied for evaluating the durability of the top layer.

The torque bond test is carried out either *in situ* or in the laboratory using cores. A circular steel plate is glued to the top road surface *in situ* or on top of a core in a laboratory. A rotational horizontal force is applied to the steel plate and the torque moment is measured. For a top layer with a thickness < 15 mm, the steel plate is glued on top of the surface or a – for the laboratory test method – a core that is larger than the plate diameter. For a top layer with a thickness ≥ 15 mm, a cylindrical groove of the same dimension as the plate is cut through the upper layer down into the bottom layer.

4.3 Shear Bond Test (SBT)

The shear bond test assesses the resistance to horizontal shear stresses in the interlayer of two road construction layers.

- The shear bond test assesses the resistance to the stresses generated primarily by traffic accelerating or braking, but also by different thermal movements when the layers are of different materials.
- The shear bond test can be applied to assess the capability of bond coats or tack coats.
- The shear bond test is suitable to evaluate the shear bond strength of construction layers with a thickness ≥ 15 mm.

Cylindrical test specimens are subjected to direct shear loading at controlled temperature with constant shear rate. The development of shear deformation and force is recorded and the maximum recorded shear stress is determined as shear strength (in MPa) at the interface between layers. The thickness of the layer above the interlayer of interest shall be ≥ 20 mm. The core shall have a (remaining) thickness of at least 70 mm below the interface. For thinner layers than 20 mm, a grooved metal plate extension can be affixed to the specimen to minimize bulging in the top layer.

4.4 Tensile Adhesion Test (TAT)

The tensile adhesion test assesses the tensile bond strength between two road construction layers.

- The test method is applicable for thin surface layers;
- The tensile adhesion test can be applied to assess the capability of bond coats or tack coats as well as the internal cohesion of the two road construction layers.

The tensile adhesion test determines the adhesion between a surface layer and the bottom layer, perpendicular to the plane of the specimen. A test-plunger is glued on the incised and ground surface of the top layer and is pulled off with a suitable tension testing device at constant test temperature and strain rate. The maximum force related to the tension area is the adhesive tension strength in MPa.

5 Specimens

The test methods to assess the interlayer bonding are either conducted on site or on specimens cored from the pavement. The interlayer bonding conditions changes after laying with time, temperature and traffic loading. Therefore, the time span between laying and testing for site tests or coring of laboratory specimens shall be considered. The time span shall be reported in the test report.

The cores shall be stored fully supported. The support on which the cores rest shall be flat and clean. Cores shall not be stacked on top of each other. Cores shall be stored in a dry room at a temperature between 15 °C and 25 °C.

The relative humidity in the storage room should not exceed 80 %.

6 Torque Bond Test (TBT)

6.1 Apparatus

6.1.1 Core cutting apparatus, suitable for cutting nominally 100 mm or 200 mm diameter cores in bituminous and hydraulically bound materials with minimum vibration, preferably using air cooling.

6.1.2 Torque meter, fitted with a reading gauge that indicates the maximum torque obtained. The device shall be calibrated over a range of 0 Nm to 400 Nm. The torque moment shall be measured to the nearest 10 Nm. The device shall be fitted with socket-fitting allowing steel plates to be fitted and removed.

6.1.3 Metal Plate of mild steel having a diameter of (95 ± 5) mm and a thickness of (14 ± 2) mm. The plate shall incorporate a fitting enabling it to be coupled to the torque meter.

NOTE Fittings of 12,7 mm and 19,05 mm have been found to be suitable.

6.1.4 Thermometer, readable to $0,1^{\circ}\text{C}$ and accurate to $0,5^{\circ}\text{C}$.

6.1.5 Steel Ruler readable to 1 mm.

6.1.6 Callipers for measurement of core diameters.

6.1.7 Watch or Timer readable and accurate to 1 s.

6.1.8 Mould for confining laboratory test specimens (e.g. a concrete cube mould).

6.1.9 Spirit Level for checking laboratory test specimens.

6.1.10 Water bath of suitable size for temperature conditioning of the specimen.

6.1.11 Oven or refrigerated incubator (optional).

6.2 Materials

6.2.1 Adhesive (a stiff adhesive, such as rapid setting epoxy resin, with sufficient strength to avoid failure within the adhesive or at the adhesive/road surface interface).

6.2.2 Mounting material (*for laboratory tests*), e.g. rapid hardening mortar, concrete or grout.

6.3 Site test method

6.3.1 General

For each test location, 6 torque bond tests are conducted to evaluate one result. The test locations shall be located within 2 m of each other at least 100 mm apart. Another number of test locations may be chosen, e.g. in order to reduce the damage to the pavement. The number shall be reported.

6.3.2 For top layer thickness ≥ 15 mm, a 100 mm diameter groove shall be cored to a depth of 20 ± 5 mm below the interface to be tested. The cores shall not be removed. Where the layer thickness of the layer above the interlayer bond of interest is less than 15 mm, no coring is needed.

6.3.3 Measure and record the core diameter at two locations approximately 90° apart using callipers and record the mean value, D , to an accuracy of 1 mm.

In the case that no groove is cored into the surface, the diameter D equals the diameter of the steel plate glued on top of the surface.

6.3.4 Ensure that all debris is removed from the rebate formed by the core barrel. Clean and dry the surface to be tested.

6.3.5 Use the adhesive to glue the metal plate to the surface of the core or the surface layer if not cored, taking care to ensure that the plate is parallel to the surface.

6.3.6 When the bonding agent has developed sufficient strength, (i.e. failure shall not occur within the adhesive), fit the torque meter to the metal plate, using adapters and extension rods as appropriate.

6.3.7 Record the pavement surface temperature in the vicinity of the test location.

6.3.8 Apply torque to the core at a steady rate so that the torque wrench sweeps an angle of 90° within (30 ± 15) s. Care shall be taken to ensure that the torque is applied parallel to the core surface (within $\pm 10^\circ$). Torque is applied to the plate until failure of the bond occurs or a torque of 400 Nm is exceeded. In later case, 6.3.9 to 6.3.11 are not applied.

6.3.9 Record the value of torque at failure, M , in Nm. Measure and record the bond interface temperature immediately after failure. Any interface that comes apart during preparation shall be deemed to have a bond strength of 0 Nm. Examine the core and substrate and record the condition of the bond interface (e.g. smooth, planar, rough or irregular) and record the mode of failure according to the classification in 6.6. Record the substrate type (e.g. asphalt or hydraulically bound surface).

6.3.10 Measure and record the depth of the failed interface from the pavement surface to an accuracy of 1mm.

6.3.11 Calculate the bond strength in accordance with 6.5.

6.4 Laboratory test method

6.4.1 Specimens shall be cored from an in-service pavement or from a slab compacted in laboratory in accordance to EN 12697-33 with a laboratory manufactured bonding layer.

Cut six cores to a minimum depth of 80 mm below the interface being tested or down to the bottom of the asphalt layers. Extract the core taking care not to damage the surface of the core or the bond interface. For top layer thickness ≥ 15 mm, the cores shall have a diameter of 100 ± 2 mm. For top layer thickness < 15 mm, the cores shall have a diameter of 200 ± 2 mm. Another number of test specimens may be chosen, e.g. in order to reduce the damage to the pavement. The number shall be reported.

If laboratory tests are to be compared to site test results, similar duration between laying of the layer on top of the bonding layer shall be applied.

NOTE The duration between laying and compaction, coring and testing influences the test results.

If immediate testing is not possible, the cores shall be stored at a temperature between 0 °C and 5 °C until testing.

6.4.2 Trim the core to a length suitable for mounting if appropriate.

prEN 12697-48:2019 (E)

6.4.3 Place the core in the mould, using mortar or grout as a bedding layer if appropriate, so that the upper layer and the bond interface to be tested is (20 ± 10) mm above the rim of the mould. Fill the mould with the mortar/grout and trim flush with the mould rim, ensuring that the core is perpendicular to, and the upper surface parallel with, the mould surface. Check using the spirit level.

6.4.4 Glue the metal plate to the core surface using the adhesive and allow to set.

6.4.5 Condition the mounted cores by storing at a temperature of (20 ± 2) °C for a minimum of 4 h before testing. Record the times and temperatures employed.

The standard test temperature is (20 ± 2) °C.

Other test temperatures may be applied for other purposes.

NOTE Example of other purpose can be when data obtained from site tests carried out at a temperature other than (20 ± 2) °C is subject to comparison.

6.4.6 Test the core at a temperature of (20 ± 2) °C. If other temperatures are used the test shall be completed within 5 min of removal from the conditioning environment.

6.4.7 Fix or clamp the mould containing the mounted core to a suitably rigid surface. Carry out the test as described in 6.3.8.

6.4.8 Examine the core and record all the relevant information as described in 6.6 and 6.7.

6.5 Calculation of Torque Bond Strength and expression of results

6.5.1 Calculate the torque bond strength τ_{TBT} for each specimen using the following formula:

$$\tau_{TBT} = \frac{12 \times M \times 10^{-6}}{\pi \times D^3} \quad \text{https://standards.iteh.ai/catalog/standards/sist/86c575da-ed48-43df-b199-aeb70c42fc7f/osist-pren-12697-48-2020} \quad (1)$$

where

- τ_{TBT} inter-layer torque shear bond strength in kilopascal (kPa)
- M peak value of applied shearing torque in Newton meter (Nm),
- D diameter of core in millimetres (mm)

6.5.2 Calculate the arithmetic mean of the torque bond strength measured on the six specimens / locations.

6.6 Visual assessment of the mode of failure

In case of failure of the interface, the visual assessment of the failed surface shall be determined according to the following classification:

- a) Within the surface layer (cohesion failure),
- b) partly at the interface, partly in the surfacing layer (mixed failure),
- c) at the interface (adhesion failure),
- d) partly in the bottom layer, partly at the interface (mixed failure),
- e) in the bottom layer (cohesion failure),
- f) partly or completely in the adhesive.

If a mixed failure is observed, the proportions of the failure modes shall be estimated with an accuracy of 10 %.

In the case, that the interface did not fail, “no failure” shall be recorded.

6.7 Test report

The test report shall include the following information:

- a) Name of organization carrying out the test;
- b) method of test used (*in situ*, laboratory) and if cored or not;
- c) description of materials (system and substrate);
- d) date of test;
- e) number of tests conducted per location or number of tested laboratory specimens;
- f) peak torque at failure (Nm) for individual cores;
- f) inter-layer torque bond strength τ_{BT} (kPa), (individual and mean values);
- g) time to failure (seconds);
- h) diameter of cores (mm) if appropriate;
- i) depths of Bond interface (mm);
- j) temperature of the pavement surface or the specimen (°C);
- k) conditioning details (duration and temperature);
- l) site or laboratory test;
- m) identification of site or scheme;
- n) specimen or location number;
- o) age of the tested interface at the time of test;
- p) mode of failure.

6.8 Precision

The precision for this test method has not been determined.

7 Shear Bond Test (SBT)

7.1 Apparatus

7.1.1 Shear test apparatus, as shown in Figure 1, composed of a base body (A) on which are fixed the sample support (B) and the lower shear ring (C). The upper shear ring (D) is attached to the upper body (E), which is movable vertically along the guiding bars (F).

A gap length ≤ 5 mm is recommended.

NOTE The gap length between shear rings influences the test results.

Key

- A base body
- B sample support
- C lower shear ring
- D upper shear ring
- E upper body
- F guiding bar

(standards.iteh.ai)

Figure 1—Schematic diagram of the Shear Bond Test apparatus

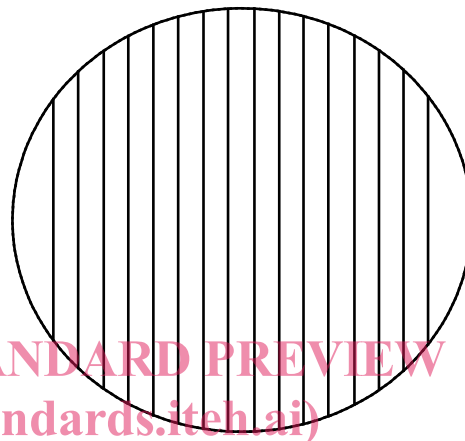

<https://standards.iteh.ai/catalog/standards/sist/86c575da-ed48-43df-b199-86c575da-ed48-43df-b199>

7.1.2 Loading frame capable of achieving a constant vertical displacement rate of $(50,0 \pm 2)$ mm per minute up to a displacement of at least 7 mm and a maximum load of at least 35 kN.

7.1.3 Data logging system to record load and displacement during the test.

7.1.4 Metal plate extension as shown in Figure 2, composed of aluminium or other metal.

7.1.5 Adhesive (a stiff adhesive, such as rapid setting epoxy resin, with sufficient strength to avoid failure within the adhesive or at the adhesive/thin surfacing interface).

iTeh STANDARD PREVIEW
(standards.iteh.ai)

Key

- 1 dimension to suit diameter of specimen

Figure 2 — Schematic diagram of the metal plate extension (example)

7.2 Specimens

7.2.1 At least two specimens shall be cored from the pavement to be tested.

7.2.2 Specimens shall be cores of (150 ± 2) mm or (100 ± 2) mm diameter. The minimum thickness of the layers above the interface to be tested shall be 20 mm and below the interface 70mm respectively. Specimens shall be cored from an in-service pavement according EN 12697-27 or from a slab manufactured using a laboratory roller compactor in accordance with EN 12697-33.

For top and/or bottom layer thickness below the requirement, a metal plate extension can be glued to the specimen.

NOTE The specimen diameter influences the test results.

7.2.3 Cores shall have constant diameters throughout their length and smooth lateral surfaces to allow adequate placement in the apparatus. The interface between layers shall be perpendicular to the core's longitudinal axis. The maximum acceptable deviation from the standard plane shall be 5 mm.

If cores taken from in-service-pavements are tested, the direction of traffic shall be marked to the cores.
