<u>SIST ISO 9096:2018</u> https://standards.iteh.ai/catalog/standards/sist/93cd1941-a1bf-4e49-a661dde5983bc71e/sist-iso-9096-2018

#### Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see <a href="https://www.iso.org/directives">www.iso.org/directives</a>).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see <a href="https://www.iso.org/patents">www.iso.org/patents</a>).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation on the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT) see the following URL: <a href="http://www.iso.org/iso/foreword.html">www.iso.org/iso/foreword.html</a>.

This document was prepared by ISO Technical Committee ISO/TC 146, *Air quality*, Subcommittee SC 1, *Stationary source emissions*.

This third edition cancels and replaces the second edition (ISO 9096:2003), of which it constitutes a minor revision. It also incorporates the Technical Corrigendum ISO 9096:2003/Cor.1:2006. The changes compared to the previous edition are as follows:

- <u>Table 3</u>: in the row entitled "Isokinetic criteria (average measurement uncertainty)" the value "±10 %" has been replaced by "<sup>+15</sup><sub>-5</sub> %" (according to ISO 9096:2003/Cor.1:2006).
- <u>Formula (11)</u>: the percent symbol has been added twice.
- <u>Formula (13)</u>: the percent symbol has been added twice.
- Figure A.2: < 0,2 has been corrected to > 0,2.
- <u>Formula (B.6)</u>: the parentheses have been removed.
- <u>Formula (B.7)</u>: the formula has been corrected.

### Introduction

Close liaison and cooperation between ISO/TC 146/SC 1 and CEN/TC 264 has resulted in the preparation of this document, ISO 12141 and EN 13824-1. This document is similar to EN 13284-1 with additional emphasis given on the use of high-volume sampling techniques. A representative, integrated sample is extracted from the flue gas and the particulate matter entrained in the gas sample is separated by a filter. The pre-weighed filter is subsequently dried and weighed. A relative increase in the mass is attributed to the collection of particulate matter on the filter.

To meet the specifications of this document, the particulate sample is weighed to a specified level of accuracy. This level of accuracy is achieved by:

- a) exercising extreme care in weighing, in accordance with the procedures of this document;
- b) extending the sampling time at conventional sampling rates;
- c) sampling at higher rates for conventional sampling times (high-volume sampling);
- d) recovering all dust upstream of the filter.

### iTeh STANDARD PREVIEW (standards.iteh.ai)

SIST ISO 9096:2018 https://standards.iteh.ai/catalog/standards/sist/93cd1941-a1bf-4e49-a661dde5983bc71e/sist-iso-9096-2018

#### FINAL DRAFT INTERNATIONAL STANDARD

## Stationary source emissions — Manual determination of mass concentration of particulate matter

#### 1 Scope

This document describes a reference method for the measurement of particulate matter (dust) concentration in waste gases of concentrations from  $20 \text{ mg/m}^3$  to  $1 000 \text{ mg/m}^3$  under standard conditions.

This document is applicable to the calibration of automated monitoring systems (AMS). If the emission gas contains unstable, reactive or semi-volatile substances, the measurement will depend on the filtration temperature. In-stack methods can be more applicable than out-stack methods for the calibration of automated monitoring systems.

#### 2 Normative references

dde5983bc71e/sist-iso-9096-2018

For the purposes of this document, the following terms and definitions apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

- ISO Online browsing platform: available at <a href="http://www.iso.org/obp">http://www.iso.org/obp</a>
- IEC Electropedia: available at <u>http://www.electropedia.org/</u>

#### 3.1 particulate matter dust

particles, of any shape, structure or density, dispersed in the gas phase under the sampling conditions

Note 1 to entry: In the method described, all the compounds that may be collected by filtration under specified conditions after representative sampling of the gas to be analysed, and which remain upstream of the filter and on the filter after drying under specified conditions, are considered to be dust (or particulate matter). However, for the purposes of some national standards, the definition of particulate matter can extend to condensibles or reaction products collected under specified conditions (e.g. temperatures lower than the flue gas temperature).

Note 2 to entry: This method restricts the definition of particulate matter to that material collected in the sampling system on and before a filter, under specified temperature conditions. Procedures for the measurement of secondary particulate matter (condensible materials) formed and collected after the filter are not within the scope of this document.

#### 3.2

#### filtration temperature

temperature of the sampled gas immediately downstream of the filter

#### 3.3

#### in-stack filtration

filtration in the duct with the filter in its filter holder placed immediately downstream of the sampling nozzle

#### 3.4

#### out-stack filtration

filtration outside of the duct with the filter in its heated filter holder placed downstream of the sampling nozzle and the suction tube (sampling probe)

#### 3.5

#### isokinetic sampling

sampling at a flowrate such that the velocity and direction of the gas entering the sampling nozzle,  $v_n$ , are the same as that of the gas in the duct at the sampling points,  $v_s$ 

Note 1 to entry: See Figure 1 and Annex D.

Note 2 to entry: The velocity ratio,  $v_n/v_s$ , expressed as a percentage characterizes the deviation from isokinetic sampling.

Key

*v*<sub>s</sub> stack gas velocity

*v*<sub>n</sub> velocity in the nozzle

(1)

#### 3.6 hydraulic diameter $d_{\rm h}$ characteristic dimension of a duct cross-section

$$d_{\rm h} = \frac{4 \times A_{\rm s}}{l_{\rm s}}$$

where

- *A*<sub>s</sub> is the cross-sectional area of the sampling plane;
- $l_{\rm s}$  is the length of the perimeter of the sampling plane.

#### 3.7

#### sampling plane

plane normal to the centreline of the duct at the sampling position

Note 1 to entry: See Figure 2.

#### Key

- 1 sampling lines
- 2 sampling plane
- 3 access port
- 4 flow
- 5 top of duct

#### 3.8

#### sampling line

line in the sampling plane (3.7) along which sampling points (3.9) are located, bounded by the inner duct wall

Note 1 to entry: See Figure 2.

#### 3.9

#### sampling point

specific position on a *sampling line* (3.8) at which a sample is extracted

#### 3.10

#### standard conditions

gas pressure and temperature constants and conditions to which volumetric calculations are referred

Note 1 to entry: For the purposes of this document, standard conditions are 101,325 kPa rounded to 101,3 kPa; 273,15 K rounded to 273 K; dry gas.

#### 3.11

#### overall blank

test sample taken at the plant site in an identical manner to the normal samples in the series, except that no gas is sampled during the test duration

Note 1 to entry: The measured mass variation provides an estimation of the uncertainties. The overall blank value, divided by the average sampling volume of the measurement series, provides an estimation of the detection limit (milligrams per cubic metre) of the whole measurement process, as carried out by the operator. The overall blank includes possible deposits on the filter and on all parts upstream.

#### 3.12

#### weighing control procedures

quality control procedures utilized for detecting/correcting apparent mass variations due to climatic or environmental changes between pre- and post-sampling weighing series

Note 1 to entry: In these procedures, control parts are used (see 7.2) which are identical to those to be weighed for dust measurement and are pre-treated under the same conditions of temperature and humidity. The control parts are kept free from dust contamination.

#### 3.13

#### measurement series

successive measurements carried out in the same *sampling plane* (<u>3.7</u>), and under the same process conditions

#### 3.14

#### limit value

dust concentration that is permitted by authorities for the plant process (i.e. average limit value)

Note 1 to entry: For purposes other than regulatory uses, the measurement value is compared to a stated reference value.

#### **4** Principle

#### 4.1 General

A sample stream of the gas is extracted from the main gas stream at specified sampling points for a measured period of time, with an isokinetic controlled flowrate. The volume of gas collected is measured, and a pre-weighed filter, which is then dried and reweighed, separates the particulate matter (dust) entrained in the gas sample. Deposits upstream of the filter in the sampling equipment are also recovered and weighed. The increase in mass of the filter and the mass deposited upstream of the filter is attributed to particulate matter collected from the sampled gas. The ratio of the mass of the particulate matter collected to the volume of gas collected allows the flue gas particulate concentration to be calculated.

Valid measurements can be achieved only when:

- an adequate quantity of dust is collected during the sampling, which is at least 5 times the a) corresponding overall blank value;
- b) the gas stream in the duct at the sampling location has a sufficiently steady and identified velocity, temperature and pressure, and a sufficiently homogeneous composition;
- the flow of gas is parallel to the axis of the nozzle; c)
- d) sampling is carried out without disturbance of the gas stream, using a sharp-edged nozzle facing into the stream;
- isokinetic sampling conditions are maintained throughout the test; e)
- samples are taken at a preselected number of stated positions in the sampling plane to obtain a f) representative sample for a non-uniform distribution of particulate matter in the duct or stack;
- the sampling train is designed and operated to avoid condensation and to be leak-free; g)
- h) calibration criteria are met;
- sampling blank and leak-check criteria are met; i)
- dust deposits upstream of the filter are recovered and/or taken into account; j)
- k) the sampling and weighing procedures are adapted to the expected dust quantities as specified in this document.

#### 4.2 Interferences

- a) Positive interference

Gaseous species present in stack gases that are capable of reacting to form particulate matter within the sample train can result in positive interference. Examples include the potential reaction of sulfur dioxide (SO<sub>2</sub>) to an insoluble sulfate compound in the high-humidity portion of the system, such as with limestone in flue gas following a wet flue-gas desulfurization system (FGDS) to form calcium sulfate (CaSO<sub>4</sub>), or the reaction with ammonia gas (NH<sub>3</sub>) to form ammonium sulfate  $(NH_4SO_4)$  [see <u>7.1</u> a)].

- b) Negative interference
  - 1) Certain acid gaseous species can erode the filter material, resulting in negative interference. For example, the reaction of hydrogen fluoride (HF) with glass components in the sample train (see <u>6.2.5</u>).
  - 2) Volatile matter existing in solid or liquid form in the stack gas may vaporize after collection on the sample train filtration material, due to continued exposure to the hot sample stream during the sampling period. This would result in a negative interference (see 8.1).

#### **5** Sampling plane and sampling points

#### 5.1 General

Representative sampling is possible when a suitable location is available, having a sufficiently homogeneous gas velocity at the sampling plane.

Sampling shall be carried out at a sufficient number of sampling points, usually located on several sampling lines. Convenient access ports and a working platform shall be available for the testing.

#### 5.2 Sampling plane

The sampling plane shall be situated in a length of straight duct (preferably vertical) with a constant shape and cross-sectional area. The sampling plane shall be as far downstream and upstream as possible from any obstruction that can cause a disturbance and produce a change in the direction of flow (disturbances caused by, for example, bends, fans or pollution abatement equipment).

#### 5.3 Requirements for sampling points

Preliminary measurements at all the sampling points defined in <u>5.4</u> and <u>Annex B</u> shall prove that the gas stream in the sampling plane meets the following requirements:

- a) the angle of gas flow is less than 15° with regard to the duct axis (a recommended method for estimation is indicated in ISO 10780:1994, Annex C);
- b) no local negative flow is present;
- c) the minimum velocity is higher than the detection limit of the method used for the flowrate measurement (for Pitot tubes, a differential pressure larger than 5 Pa);
- d) the ratio of the highest to lowest local gas velocities is less than 3:1.

If the above requirements cannot be met, the uncertainty is higher than that specified by this document and the sampling location is not in compliance with this document (see <u>7.4.6</u>).

The above requirements are generally met in sections of duct with at least five hydraulic diameters of straight duct upstream of the sampling plane and two hydraulic diameters downstream (five hydraulic diameter from the top of a stack). Therefore, it is strongly recommended that sampling locations be selected accordingly.

ected accordingly.ps://standards.iteh.ai/catalog/standards/sist/93cd1941-a1bf-4e49-a661-

#### dde5983bc71e/sist-iso-9096-20

#### 5.4 Minimum number and location of sampling points

The dimensions of the sampling plane dictate the minimum number of sampling points. In general, this number increases as the duct dimensions increase.

<u>Tables 1</u> and <u>2</u> give the minimum number of sampling points to be used for circular and rectangular ducts respectively. The sampling points shall be located at the centres of equal areas in the sampling plane (in accordance with <u>Annex B</u>).

Sampling points shall not be located within 3 % of the sampling line length (if d > 1,5 m) or 5 cm (if d < 1,5 m) from the inner duct wall. Choose the inner edge of the area when calculations result in sampling point positions within this area. This may arise when selecting more than the minimum numbers of sampling points presented in Tables 1 and 2, for example in cases of unusual duct shape.

NOTE When the requirements for the sampling plane (see 5.2) cannot be met, it is sometimes possible to improve representative sampling by increasing the number of sampling points above those specified in <u>Tables 1</u> and <u>2</u>. See also <u>7.3.2</u> for sampling-point premeasurement procedures.

Range of duct diameters	Minimum number of sampling lines	Minimum number of sampling points per line		Minimum number of sampling points per plane

<sup>a</sup> Other side divisions can be necessary, for example if the longest duct side length is more than twice the length of the shortest side.

<sup>b</sup> Using only one sampling point can give rise to errors greater than those specified in this document.

#### 5.5 Access ports

T ISO 9096·2018

Ports shall be provided for access to the sampling points selected in accordance with <u>Annex B</u>.

The port dimensions shall provide space for the insertion and removal of the sampling equipment and associated devices, and allow for sealing once the sampling equipment is in place. A minimum diameter of 125 mm or a surface area of 100 mm  $\times$  250 mm are recommended, except for small ducts (less than 0,7 m diameter) for which the port size needs to be smaller (see <u>Annex F</u> for examples).

#### 5.6 Sampling time

Assuming a volumetric flowrate characteristic of the sampling train to be used, a sampling time can be calculated that will lead to the collection of a desired or required mass of particulate matter if the approximate particulate concentration is known previously.

If the expected dust concentration,  $c_{exp}$  has been previously determined or assumed, and the mass of particulate matter, m, to be collected is required or set, then the necessary volume of the flue gas to be sampled is:

$$V_{\rm n} = \frac{m}{c_{\rm exp}} \tag{2}$$

However, the volume of the sample,  $V_n$  (litres), will be equal to the total sampling time, t (min), multiplied by the nozzle volumetric flowrate under actual conditions,  $Q_a$  (l/min), i.e.  $V_n = tQ_a$ .

The total sampling time in the sampling plane is thus estimated to be:

$$t = \frac{V_{\rm n}}{Q_{\rm a}}$$
 or  $t = \frac{m}{c_{\rm exp} \cdot Q_{\rm a}}$  (3)
