This document is not an ASTM standard and is intended only to provide the user of an ASTM standard an indication of what changes have been made to the previous version. Because it may not be technically possible to adequately depict all changes accurately, ASTM recommends that users consult prior editions as appropriate. In all cases only the current version of the standard as published by ASTM is to be considered the official document.

Designation: C769-98 (Reapproved 2005) Designation: C 769 - 09

An American National Standard

# Standard Test Method for Sonic Velocity in Manufactured Carbon and Graphite Materials for Use in Obtaining <del>an Approximate</del> Young's Modulus<sup>1</sup>

This standard is issued under the fixed designation C 769; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon ( $\varepsilon$ ) indicates an editorial change since the last revision or reapproval.

### 1. Scope

1.1This test method covers a procedure for measuring the sonic velocity in manufactured carbon and graphite materials having a grain size less than 0.80 mm (1/32 in.). The sonic velocity can be used to obtain an approximate value for Young's modulus. 1.2The values stated in SI units are to be regarded as the standard.

1.1 This test method covers a procedure for measuring the sonic velocity in manufactured carbon and graphite which can be used to obtain Young's modulus.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

#### 3. Terminology

3.1 Definitions of Terms Specific to This Standard:

3.1.1 <u>end correction time ( $T_e$ )</u>—the non-zero time of flight (correction factor), measured in seconds, that may arise by extrapolation of the pulse travel time, corrected for zero time, back to zero sample length.

<u>3.1.2</u> longitudinal sonic pulse—a sonic pulse in which the displacements are in the direction of propagation of the pulse.  $\frac{3.1.2}{3.1.2}$ 

<u>3.1.3</u> pulse travel time,  $(T_t)$ —the total time, measured in seconds, required for the sonic pulse to traverse the specimen being tested, and for the associated electronic signals to traverse the <u>transducer coupling medium and electronic</u> circuits of the pulse-propagation <del>circuitry.</del>system.

3.1.33.1.4 zero time,  $(T_{0}0)$ —the travel time (correction factor), measured in seconds, associated with the transducer coupling medium and electronic circuits in the pulse-propagation system.

## 4. Summary of Test Method

4.1 The velocity of <u>longitudinal</u> sound waves passing through the test specimen is determined by measuring the distance through the specimen and dividing by the time lapse, between the transmitted pulse and the received pulse.<sup>3,4</sup> An approximate value for <u>Young's modulus can then be obtained as follows:</u> Provided the wavelength of the transmitted pulse is a sufficiently small fraction of the sample later dimensions, a value of Young's modulus for isotropic graphite can then be obtained using Eq 1 and Eq 2:

 $(1) \quad E = Cv\rho V 2$  $(1) \quad E = Cv\rho V 2$  $\underline{C0769-09\_1}$ 

where:

E = Young's modulus of elasticity, Pa,

 $\rho$  = density, kg/m<sup>3</sup>, and,

vV = signal velocity, m/s. longitudinal signal velocity, m/s, and

 $\underline{C}_{\nu} \equiv \underline{Poisson's factor.}$ 

Strictly speaking, the elastic constant given by this measurement is not E but  $C_{33}$ , provided the sonic pulse is longitudinal and the direction of propagation is along the axis of symmetry.<sup>3,4</sup>

The Poisson's factor,  $C_{\nu}$ , is related to Poisson's ratio,  $\nu$ , by the equation:

$$C_{\nu} = \frac{(1+\nu)(1-2\nu)}{1-\nu}$$
(2)

If Poisson's ratio is unknown, it can be assumed as an approximation in the method. For nuclear graphites, a typical Poisson's ratio of 0.2 corresponds to a Poisson's factor of 0.9.

If the wavelength is not a small fraction of the sample lateral dimensions, and instead is much larger than the specimen lateral dimensions, then the Young's modulus, E is given by Eq 1 with  $C_{\nu}$  set to one rather than being determined by Eq 2.

## 5. Significance and Use

5.1 Sonic velocity measurements are useful for comparing materials.

5.2A value for Young's modulus can be obtained for many applications, which will generally be within 10% of the value obtained by other methods, such as in Test Method C747.

5.2 A value for Young's modulus can be obtained for many applications, which will be in good agreement with the value obtained by other methods, such as in Test Method C 747. The accuracy of the Young's modulus calculated from Eq 1 will depend upon the uncertainty in Poisson's ratio and its impact on the evaluation of the Poisson's factor in Eq 2.

5.3 If the grain size of the carbon or graphite is greater than or about equal to the wavelength of the sonic pulse, the method may not be providing a value of Young's modulus representative of the bulk material. Therefore, it would be desirable to test a lower frequency (longer wavelength) to demonstrate that velocity is independent of frequency. Significant signal attenuation should be expected when the grain size of the material is greater than or about equal to the wavelength of the transmitted sonic pulse.

5.4 If the sample is only a few grains thick, the acceptability of the method's application should be demonstrated by initially performing measurements on a series of tests covering a range of sample lengths between the proposed test length and a test length incorporating sufficient grains to adequately represent the bulk material.

6. Apparatus/standards.iteh.ai/catalog/standards/sist/e3ad8cd5-394e-4f3d-8946-c174eed80a6e/astm-c769-09

6.1 Driving Circuit, which consists of an ultrasonic pulse generator capable of producing pulses in a frequency range from 0. 5 to 2.6 MHz., consisting of an ultrasonic pulse generator.

<u>6.1.1</u> The user should select a pulse frequency to suit the material being tested. High frequencies are attenuated by carbon and graphite materials and, while typical practicable frequencies lie in the range 0.5 to 2.6 MHz, the user may show that frequencies outside this range are acceptable.

6.2 Transducer, input., input, with suitable coupling medium (see 8.5).

6.3 Transducer, output.

6.4Oscilloscope, dual tracewith a preamplifier and time-delay circuitry.

6.5See-, output, with suitable coupling medium (see 8.5).

<u>6.3.1</u> The signal output will depend upon the characteristics of the chosen transducers and the test material. It is recommended that the user analyses the input and output frequency spectra to determine optimum conditions. Band pass filters and narrow band transducers may be used to simplify the signal output which could improve the measurement of the time of flight.

6.4 Computer, with analogue to digital converter, or oscilloscope, and external trigger from driving circuit.

6.5 See Fig. 1for a typical setup. for a typical schematic setup.

NOTE 1—Some manufacturers combine items 6.1 and 6.4 into a single package with direct time readout. Such apparatus can operate satisfactorily, provided the frequency of the propagated pulse is already known, in order to check that wavelength requirements for the method are satisfied.

# 7. Test Specimen

7.1 Selection and Preparation of Specimens—Take special care to assure obtaining representative specimens that are straight, uniform in cross section, and free of extraneous liquids. The specimen end faces shall be perpendicular to the specimen cylindrical surface to within 0.125 mm (0.005 in.)-total indicator reading.

7.2 Measurement of Weight and Dimensions — Determine the weight and the average specimen dimensions to within  $\pm 0.5\%$ .  $\pm 0.2\%$ . 🖽 C 769 – 09

FIG. 1 Basic Experimental Arrangement for the Ultrasonic Pulsed-Wave Transit Time Technique

7.3 Limitations on Dimensions—The specimen shall have a diameter and length that is large compared to the wavelength of sound in the material under test. —These cannot be precisely specified as they will depend upon the properties of the material being tested. In order to satisfy the theory that supports Eq 1, as a guide, the specimen should have a diameter that is at least a factor two, and ideally a factor five, greater than the wavelength of sound in the material under test. In practice, the length of the specimen will be determined taking account of the comments in 5.3 and 5.4.

7.4 *Limitations on Ultrasonic Pulse Frequency*—Generally speaking, a better accuracy of time of flight will be obtained at higher frequencies. However, attenuation increases at higher frequencies leading to weak and distorted signals.

### 8. Procedure

8.1Connect the apparatus as shown in

8.1 For any given apparatus and choice of coupling medium, it is necessary to follow procedures to quantify the zero time,  $T_0$ , and end correction time,  $T_e$ , correction factors.  $T_0$  will be dependent upon the type of transducers and their performance over time and should be regularly checked (see 8.8). It must be quantified if the test set up is changed.  $T_e$  should be small and reflects the interaction between the coupling medium and the test material.  $T_e$  should be determined once for a specific measurement setup and test material.

<u>8.1.1</u> Determine whether an end correction time,  $T_e$ , is evident in the time of flight by performing time of flight measurements on various length samples taken from a single bar. As modulus is likely to vary from sample to sample the recommended approach is to continually bisect a long rod, measuring each bi-section, until the required lower limit is reached. The end correction time,  $T_e$ , is obtained from a regression fit to a graph of time of flight versus sample length.

8.2 Measure and weigh the test specimen as in 7.2.

8.3 Calculate the density of the test specimen in accordance with Test Method C 559.

<u>8.4</u> Connect the apparatus as shown in Fig. 1, and refer to equipment manufacturers instructions for hookup precautions. Allow adequate time for equipment warm-up and stabilization.

8.2Provide a suitable coupling medium on transducer faces., and refer to equipment manufacturer's instructions for setup precautions. Allow adequate time for equipment warm-up and stabilization.

8.5 Place the transducers against the test specimen end faces.

<u>8.5.1 A coupling medium may be necessary to improve transmission of the sonic pulse. In this case, apply a light coating of the coupling medium to the faces of the test specimens that will contact the transducers. Alternatively, "soft rubber" tipped transducers can be effective if a fully noninvasive measurement is needed.</u>

NOTE1-Hydroxyethyl cellulose may be used. Petroleum jelly couples work well but may be difficult to remove for subsequent tests on the same specimen.

8.3Bring transducer faces into intimate contact but do not exceed manufacturer's recommended contact pressures.

8.4Determine 2—The following coupling media may be used: hydroxyethyl cellulose, petroleum jelly, high vacuum greases and water-based ultrasonic couplants. However these may be difficult to remove subsequently. Distilled water can provide a very satisfactory coupling medium without significant end effects, and surface water may be removed subsequently by drying. Manufacturers offer soft rubber-tipped transducers suitable for noninvasive measurements. With these transducers either good load control or accurate determination of the soft rubber length is essential during measurement if good reproducibility is to be achieved.

8.6 Bring transducer faces into intimate contact but do not exceed manufacturer's recommended contact pressures.
