

Designation: D143 – 09

Standard Test Methods for Small Clear Specimens of Timber¹

This standard is issued under the fixed designation D143; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

INTRODUCTION

The need to classify wood species by evaluating the physical and mechanical properties of small clear specimens has always existed. Because of the great variety of species, variability of the material, continually changing conditions of supply, many factors affecting test results, and ease of comparing variables, the need will undoubtedly continue to exist.

In the preparation of these methods for testing small clear specimens, consideration was given both to the desirability of adopting test methods that would yield results comparable to those already available and to the possibility of embodying such improvements as experience has shown desirable. In view of the many thousands of tests made under a single comprehensive plan by the U.S. Forest Service, the former Forest Products Laboratories of Canada (now Forintek Canada Corp.), and other similar organizations, these test methods naturally conform closely to the methods used by those institutions. These test methods are the outgrowth of a study of both American and European experience and methods. The general adoption of these test methods will tend toward a world-wide unification of results, permitting an interchange and correlation of data, and establishing the basis for a cumulative body of fundamental information on the timber species of the world.

Descriptions of some of the strength tests refer to primary methods and secondary methods. Primary methods provide for specimens of 2 by 2-in. (50 by 50-mm) cross section. This size of specimen has been extensively used for the evaluation of various mechanical and physical properties of different species of wood, and a large number of data based on this primary method have been obtained and published.

The 2 by 2-in. (50 by 50-mm) size has the advantage in that it embraces a number of growth rings, is less influenced by earlywood and latewood differences than smaller size specimens, and is large enough to represent a considerable portion of the sampled material. It is advisable to use primary method specimens wherever possible. There are circumstances, however, when it is difficult or impossible to obtain clear specimens of 2 by 2-in. cross section having the required 30 in. (760 mm) length for static bending tests. With the increasing incidence of smaller second growth trees, and the desirability in certain situations to evaluate a material which is too small to provide a 2 by 2-in. cross section, a secondary method which utilizes a 1 by 1-in. (25 by 25-mm) cross section has been included. This cross section is established for compression parallel to grain and static bending tests, while the 2 by 2-in. cross section is retained for impact bending, compression perpendicular to grain, hardness, shear parallel to grain, cleavage, and tension perpendicular to grain. Toughness and tension parallel to grain are special tests using specimens of smaller cross section.

The user is cautioned that test results between two different sizes of specimens are not necessarily directly comparable. Guidance on the effect of specimen size on a property being evaluated is beyond the scope of these test methods and should be sought elsewhere.

Where the application, measurement, or recording of load and deflection can be accomplished using electronic equipment and computerized apparatus, such devices are encouraged, providing they do not lower the standard of accuracy and reliability available with basic mechanical equipment.

1. Scope

1.1 These test methods cover the determination of various strength and related properties of wood by testing small clear specimens.

1.1.1 These test methods represent procedures for evaluating the different mechanical and physical properties, controlling factors such as specimen size, moisture content, temperature, and rate of loading.

1.1.2 Sampling and collection of material is discussed in Practice [D5536](#). Sample data, computation sheets, and cards have been incorporated, which were of assistance to the investigator in systematizing records.

1.1.3 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard. When a weight is prescribed, the basic inch-pound unit of weight (lbf) and the basic SI unit of mass (Kg) are cited.

1.2 The procedures for the various tests appear in the following order:

	Sections
Photographs of Specimens	5
Control of Moisture Content and Temperature	6
Record of Heartwood and Sapwood	7
Static Bending	8
Compression Parallel to Grain	9
Impact Bending	10
Toughness	11
Compression Perpendicular to Grain	12
Hardness	13
Shear Parallel to Grain	14
Cleavage	15
Tension Parallel to Grain	16
Tension Perpendicular to Grain	17
Nail Withdrawal	18
Specific Gravity and Shrinkage in Volume	19
Radial and Tangential Shrinkage	20
Moisture Determination	21
Permissible Variations	22
Calibration	23

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Summary of Test Methods

3.1 The mechanical tests are static bending, compression parallel to grain, impact bending toughness, compression perpendicular to grain, hardness, shear parallel to grain ([Note 1](#)), cleavage, tension parallel to grain, tension-perpendicular-to-grain, and nail-withdrawal tests. These tests may be made on both green and air-dry material as specified in these test methods. In addition, test methods for evaluating such physical properties as specific gravity, shrinkage in volume, radial shrinkage, and tangential shrinkage are presented.

NOTE 1—The test for shearing strength perpendicular to the grain (sometimes termed “vertical shear”) is not included as one of the principal mechanical tests since in such a test the strength is limited by the shearing resistance parallel to the grain.

4. Significance and Use

4.1 These test methods cover tests on small clear specimens of wood that are made to provide the following:

4.1.1 Data for comparing the mechanical properties of various species,

4.1.2 Data for the establishment of correct strength functions, which in conjunction with results of tests of timbers in structural sizes (see Test Methods [D198](#) and Test Methods [D4761](#)), afford a basis for establishing allowable stresses, and

4.1.3 Data to determine the influence on the mechanical properties of such factors as density, locality of growth, position in cross section, height of timber in the tree, change of properties with seasoning or treatment with chemicals, and change from sapwood to heartwood.

5. Photographs of Specimens

5.1 Four of the static bending specimens from each species shall be selected for photographing, as follows: two average growth, one fast growth, and one slow growth. These specimens shall be photographed in cross section and on the radial and tangential surfaces. [Fig. 1](#) is a typical photograph of a cross section of 2 by 2-in. (50 by 50-mm) test specimens, and [Fig. 2](#) is the tangential surface of such specimens.

6. Control of Moisture Content and Temperature

6.1 In recognition of the significant influence of temperature and moisture content on the strength of wood, it is highly desirable that these factors be controlled to ensure comparable test results.

6.2 *Control of Moisture Content*—Specimens for the test in the air-dry condition shall be dried to approximately constant weight before test. Should any changes in moisture content occur during final preparation of specimens, the specimens shall be reconditioned to constant weight before test. Tests

FIG. 1 Cross Sections of Bending Specimens Showing Different Rates of Growth of Longleaf Pine (2 by 2-in. (50 by 50-mm) Specimens)

FIG. 2 Tangential Surfaces of Bending Specimens of Different Rates of Growth of Jeffrey Pine 2 by 2-in. (50 by 50 by 760-mm) Specimens

shall be carried out in such manner that large changes in moisture content will not occur. To prevent such changes, it is desirable that the testing room and rooms for preparation of test specimens have some means of humidity control.

6.3 *Control of Temperature*—Temperature and relative humidity together affect wood strength by fixing its equilibrium moisture content. The mechanical properties of wood are also affected by temperature alone. When tested, the specimens shall be at a temperature of $68 \pm 6^\circ\text{F}$ ($20 \pm 3^\circ\text{C}$). The temperature at the time of test shall in all instances be recorded as a specific part of the test record.

7. Record of Heartwood and Sapwood

7.1 *Proportion of Sapwood*—The estimated proportion of sapwood present should be recorded for each test specimen.

8. Static Bending

8.1 *Size of Specimens*—The static bending tests shall be made on 2 by 2 by 30 in. (50 by 50 by 760 mm) primary method specimens or 1 by 1 by 16 in. (25 by 25 by 410 mm) secondary method specimens. The actual height and width at the center and the length shall be measured (see 22.2).

8.2 *Loading Span and Supports*—Use center loading and a span length of 28 in. (710 mm) for the primary method and 14 in. (360 mm) for the secondary method. These spans were established in order to maintain a minimum span-to-depth ratio of 14. Both supporting knife edges shall be provided with bearing plates and rollers of such thickness that the distance from the point of support to the central plane is not greater than the depth of the specimen (Fig. 3). The knife edges shall be adjustable laterally to permit adjustment for slight twist in the specimen (Note 2).

NOTE 2—Details of laterally adjustable supports may be found in Fig. 1 of Test Methods D3043.

8.3 *Bearing Block*—A bearing block of the form and size of that shown in Fig. 4 shall be used for applying the load for primary method specimens. A block having a radius of 1½ in. (38 mm) for a chord length of not less than 2 in. (50 mm) shall be used for secondary method specimens.

8.4 *Placement of Growth Rings*—The specimen shall be placed so that the load will be applied through the bearing block to the tangential surface nearest the pith.

8.5 *Speed of Testing*—The load shall be applied continuously throughout the test at a rate of motion of the movable crosshead of 0.10 in. (2.5 mm)/min (see 22.3), for primary method specimens, and at a rate of 0.05 in. (1.3 mm)/min for secondary method specimens.

8.6 *Load-Deflection Curves:*

8.6.1 Load-deflection curves shall be recorded to or beyond the maximum load for all static bending tests. The curves shall be continued to a 6 in. (150 mm) deflection, or until the specimen fails to support a load of 200 lbf (890 N) for primary method specimens, and to a 3 in. (76 mm) deflection, or until

FIG. 4 Details of Bearing Block for Static Bending Tests

the specimen fails to support a load of 50 lbf (220 N) for secondary method specimens.

8.6.2 Deflections of the neutral plane at the center of the length shall be taken with respect to points in the neutral plane above the supports. Alternatively, deflection may be taken relative to the tension surface at midspan. However, take care to ensure that vertical displacements which may occur at the reactions are accounted for.

ASTM D143-09

<https://standards.iteh.ai/catalog/standards/sist/f9bade60-d189-4962-a48d-6ea4af563880/astm-d143-09>

FIG. 3 Static Bending Test Assembly Showing Test Method of Load Application, Specimen Supported on Rollers and Laterally Adjustable Knife Edges, and Test Method of Measuring Deflection at Neutral Axis by Means of Yoke and Dial Attachment (Adjustable scale mounted on loading head is used to measure increments of deformation beyond the dial capacity.)

8.6.3 Within the proportional limit, deflection readings shall be taken to 0.001 in. (0.02 mm). After the proportional limit is reached, less refinement is necessary in observing deflections, but it is convenient to read them by means of the dial gage (Fig. 3) until it reaches the limit of its capacity, normally approximately 1 in. (25 mm). Where deflections beyond 1 in. are encountered, the deflections may be measured by means of the scale mounted on the loading head (Fig. 3) and a wire mounted at the neutral axis of the specimen of the side opposite the

yoke. Deflections are read to the nearest 0.01 in. (0.2 mm) at 0.10 in. (2.5 mm) intervals and also after abrupt changes in load.

8.6.4 The load and deflection of first failure, the maximum load, and points of sudden change shall be read and shown on the curve sheet (Note 3) although they may not occur at one of the regular load or deflection increments.

NOTE 3—See Fig. 5 for a sample static bending data sheet form.

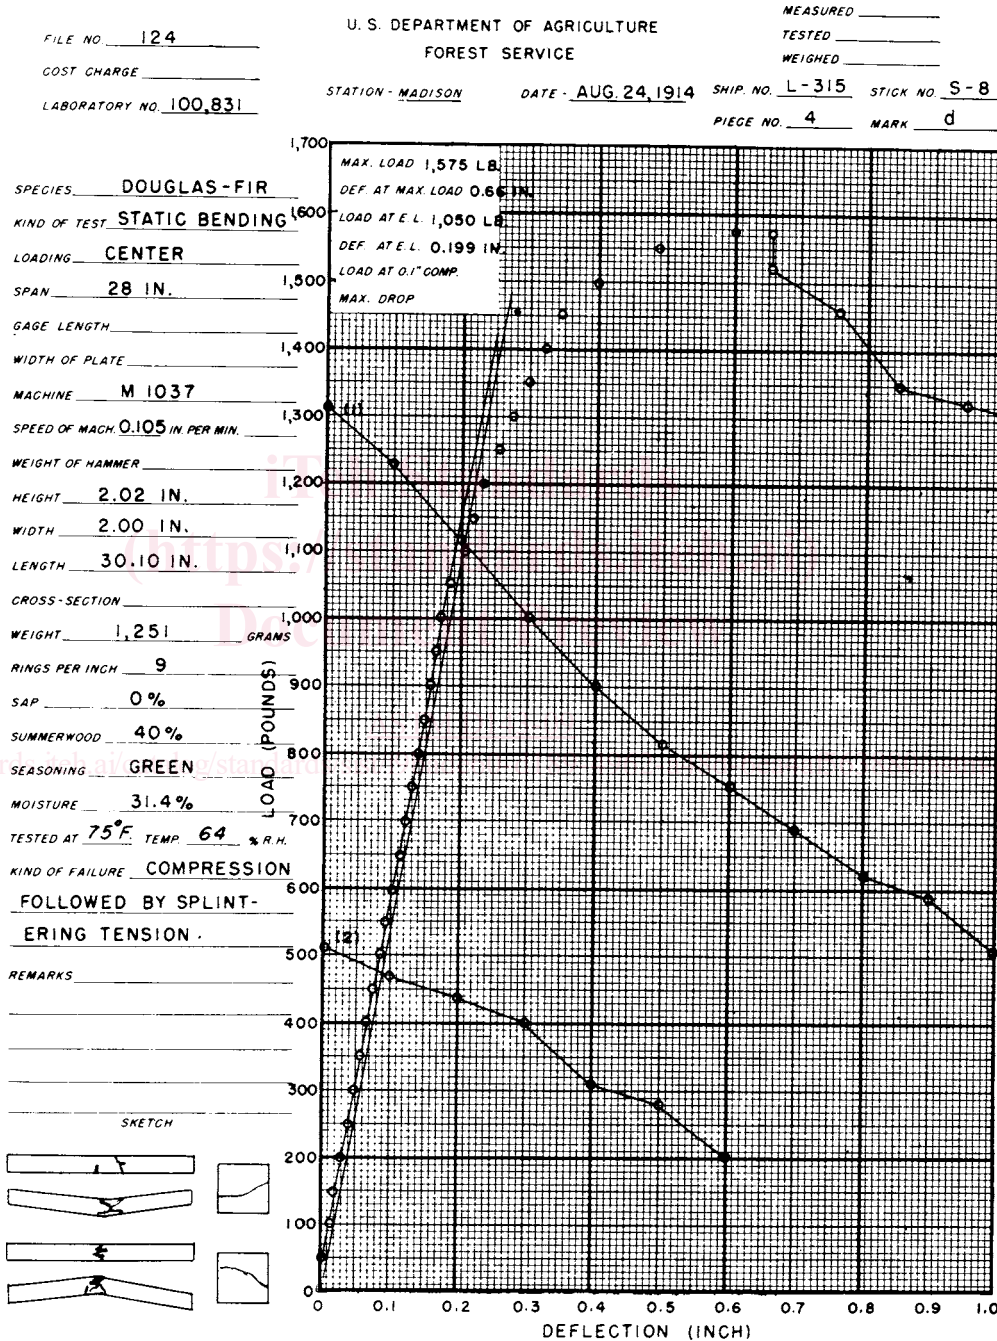

FIG. 5 Sample Data Sheet for Static Bending Test

8.7 *Description of Static Bending Failures*—Static bending (flexural) failures shall be classified in accordance with the appearance of the fractured surface and the manner in which the failure develops (Fig. 6). The fractured surfaces may be roughly divided into “brash” and “fibrous”, the term “brash” indicating abrupt failure and “fibrous” indicating a fracture showing splinters.

8.8 *Weight and Moisture Content*—The specimen shall be weighed immediately before test, and after the test a moisture section approximately 1 in. (25 mm) in length shall be cut from the specimen near the point of failure (see 21.1 and 22.1).

9. Compression Parallel to Grain

9.1 *Size of Specimens*—The compression-parallel-to-grain tests shall be made on 2 by 2 by 8 in. (50 by 50 by 200 mm) primary method specimens, or 1 by 1 by 4 in. (25 by 25 by 100 mm) secondary method specimens. The actual cross-sectional dimensions and the length shall be measured (see 22.2).

9.2 *End Surfaces Parallel*—Special care shall be used in preparing the compression-parallel-to-grain test specimens to ensure that the end grain surfaces will be parallel to each other and at right angles to the longitudinal axis. At least one platen

of the testing machine shall be equipped with a spherical bearing to obtain uniform distribution of load over the ends of the specimen.

9.3 *Speed of Testing*—The load shall be applied continuously throughout the test at a rate of motion of the movable crosshead of 0.003 in./in. (mm/mm) of nominal specimen length/min (see 22.3).

9.4 Load-Compression Curves:

9.4.1 Load-compression curves shall be taken over a central gage length not exceeding 6 in. (150 mm) for primary method specimens, and 2 in. (50 mm) for secondary method specimens. Load-compression readings shall be continued until the proportional limit is well passed, as indicated by the curve (Note 4).

NOTE 4—See Fig. 7 for a sample compression-parallel-to-grain data sheet form.

9.4.2 Deformations shall be read to 0.0001 in. (0.002 mm).

9.4.3 Figs. 8 and 9 illustrate two types of compressometers that have been found satisfactory for wood testing. Similar apparatus is available for measurements of compression over a 2 in. (50 mm) gage length.

9.5 *Position of Test Failures*—In order to obtain satisfactory and uniform results, it is necessary that the failures be made to develop in the body of the specimen. With specimens of uniform cross section, this result can best be obtained when the ends are at a very slightly lower moisture content than the body. With green material, it will usually suffice to close-pile the specimens, cover the body with a damp cloth, and expose the ends for a short time. For dry material, it may sometimes be advisable to pile the specimens in a similar manner and place them in a desiccator, should the failures in test indicate that a slight end-drying is necessary.

9.6 *Descriptions of Compression Failures*—Compression failures shall be classified in accordance with the appearance of the fractured surface (Fig. 10). In case two or more kinds of failures develop, all shall be described in the order of their occurrence; for example, shearing followed by brooming. The failure shall also be sketched in its proper position on the data sheet.

9.7 *Weight and Moisture Content*—See 8.8.

9.8 *Ring and Latewood Measurement*—When practicable, the number of rings per inch (average ring width in millimetres) and the proportion of summerwood shall be measured over a representative inch (centimetre) of cross section of the test specimen. In determining the proportion of summerwood, it is essential that the end surface be prepared so as to permit accurate latewood measurement. When the fibers are broomed over at the ends from sawing, a light sanding, planing, or similar treatment of the ends is recommended.

10. Impact Bending

10.1 *Size of Specimens*—The impact bending tests shall be made on 2 by 2 by 30 in. (50 by 50 by 760 mm) specimens. The actual height and width at the center and the length shall be measured (see 22.2).

NOTE 1—The term “cross grain” shall be considered to include all deviations of grain from the direction of the longitudinal axis or longitudinal edges of the specimen. It should be noted that spiral grain may be present even to a serious extent without being evident from a casual observation.

NOTE 2—The presence of cross grain have a slope that deviates more than 1 in 20 from the longitudinal edges of the specimen shall be cause for culling the test.

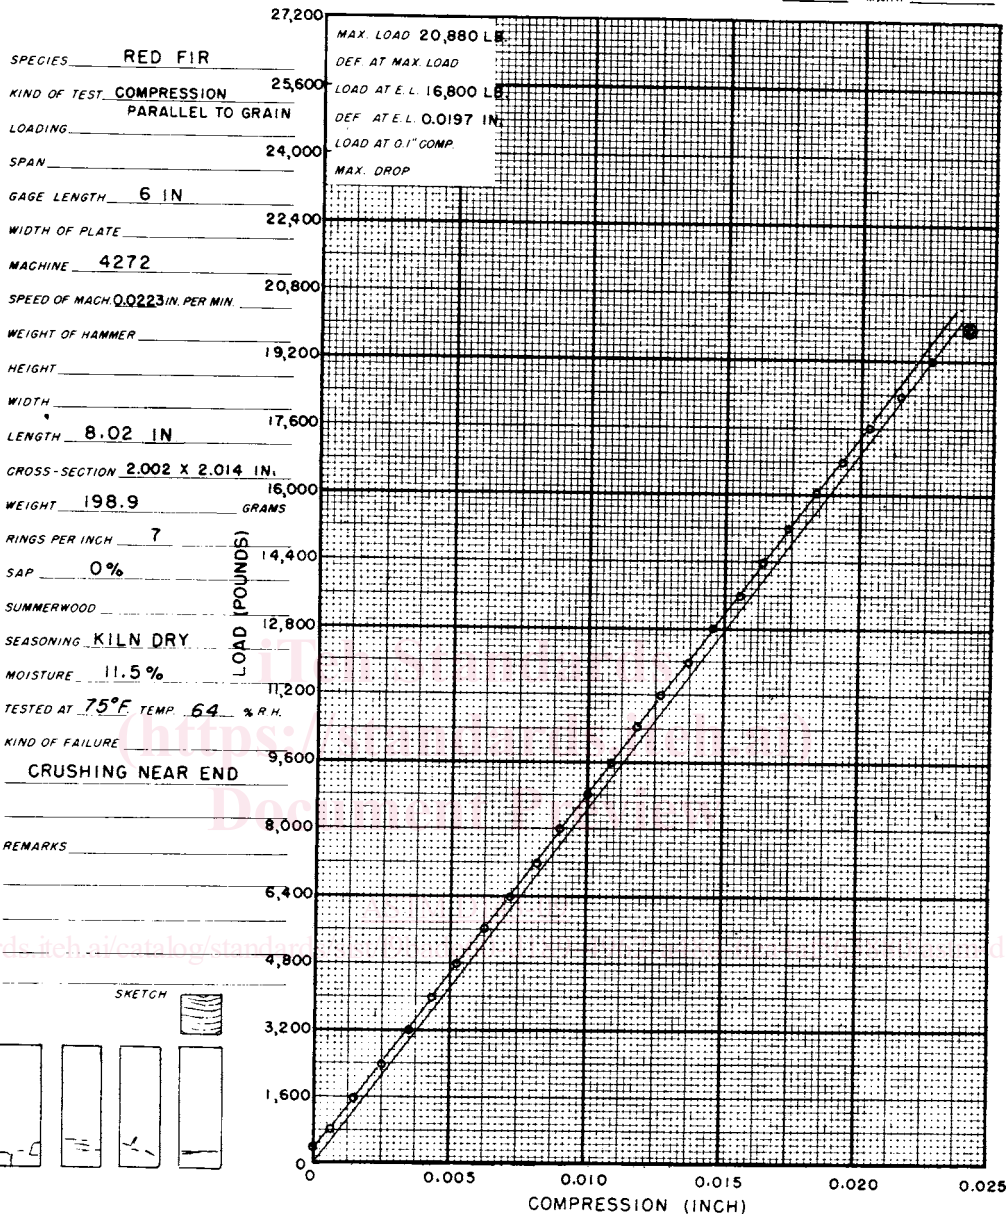

FIG. 7 Sample Data Sheet for Compression-Parallel-to-Grain Test

10.2 *Loading and Span*—Use center loading and a span length of 28 in. (710 mm).

10.3 *Bearing Block*—A metal tup of curvature corresponding to the bearing block shown in Fig. 4 shall be used in applying the load.

10.4 *Placement of Growth Rings*—The specimen shall be placed so that the load will be applied through the bearing block to the tangential surface nearest the pith.

10.5 *Procedure*—Make the tests by increment drops in a Hatt-Turner or similar impact machine (see Fig. 11). The first

drop shall be 1 in. (25 mm), after which increase the drops by 1 in. increments until a height of 10 in. (250 mm) is reached. Then use a 2 in. (50 mm) increment until complete failure occurs or a 6 in. (150 mm) deflection is reached.

10.6 *Weight of Hammer*—A 50 lbf (22.5 kg) hammer shall be used when, with drops up to the capacity of the machine (about 68 in. (1.7 m) for the small Hatt-Turner impact machine), it is practically certain that complete failure or a 6 in. (150 mm) deflection will result for all specimens of a species. For all other cases, a 100 lbf (45 kg) hammer shall be used.

FIG. 8 Compression-Parallel-to-Grain Test Assembly Using an Automatic Type of Compressometer to Measure Deformations (The wire in the lower right-hand corner connects the compressometer with the recording unit.)

FIG. 9 Compression-Parallel-to-Grain Test Assembly Showing Method of Measuring Deformations by Means of Roller-Type Compressometer

10.7 *Deflection Records*—When desired, graphical drum records (Note 5) giving the deflection for each drop and the set, if any, shall be made until the first failure occurs. This record will also afford data from which the exact height of drop can be scaled for at least the first four falls.

NOTE 5—See Fig. 12 for a sample drum record.

10.8 *Drop Causing Failure*—The height of drop causing either complete failure or a 6 in. (150 mm) deflection shall be observed for each specimen.

10.9 *Description of Failure*—The failure shall be sketched on the data sheet (Note 6) and described in accordance with the directions for static bending in 8.7.

NOTE 6—See Fig. 13 for a sample impact bending data sheet form. Fig. 14 shows a sample data and computation card.

10.10 *Weight and Moisture Content*—See 8.8.

11. Toughness

11.1 A single-blow impact test on a small specimen is recognized as a valuable and desirable test. Several types of machines such as the Toughness, Izod and Amsler have been used, but insufficient information is available to decide whether one procedure is superior to another, or whether the results by the different test methods can be directly correlated. If the Toughness machine is used, the following procedure has been found satisfactory. To aid in standardization and to facilitate comparisons, the size of the toughness specimen has been made equal to that accepted internationally.

11.2 *Size of Specimen*—The toughness tests shall be made on 0.79 by 0.79 by 11 in. (20 by 20 by 280 mm) specimens. The actual height and width at the center and the length shall be measured (see 22.2).

11.3 *Loading and Span*—Center loading and a span length of 9.47 in. (240 mm) shall be used. The load shall be applied to a radial or tangential surface on alternate specimens.

11.4 *Bearing Block*—An aluminum tup (Fig. 15) having a radius of $\frac{3}{4}$ in. (19 mm) shall be used in applying the load.

11.5 *Apparatus and Procedure*—Make the tests in a pendulum type toughness machine (Note 7) (See Fig. 15). Adjust the machine before test so that the pendulum hangs vertically, and adjust it to compensate for friction. Adjust the cable so that the load is applied to the specimen when the pendulum swings to

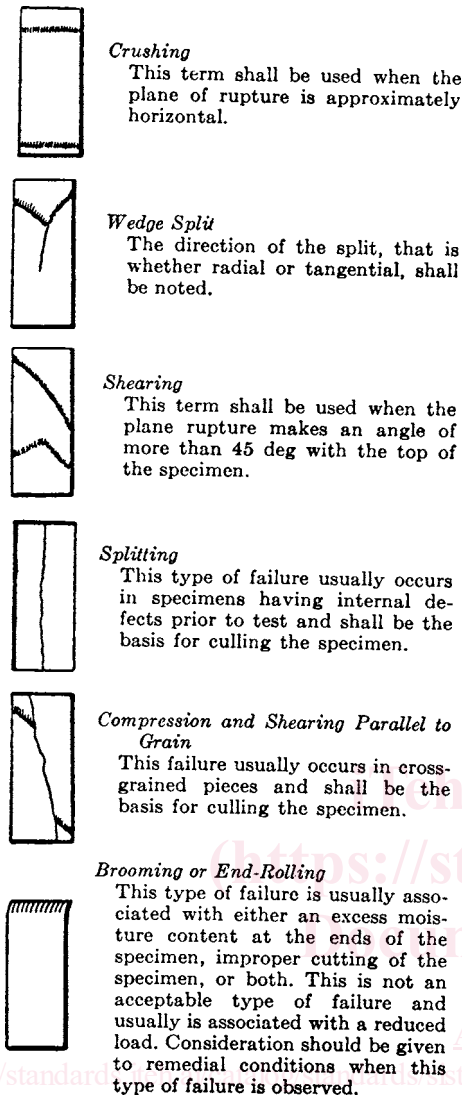

FIG. 10 Types of Failures in Compression

15° from the vertical, so as to produce complete failure by the time the downward swing is completed. Choose the weight position and initial angle (30, 45, or 60°) of the pendulum, so that complete failure of the specimen is obtained on one drop. Most satisfactory results are obtained when the difference between the initial and final angle is at least 10°.

NOTE 7—Many pendulum-type toughness machines are based on a design developed and used at the USDA Forest Products Laboratory in Madison, Wisconsin.

11.6 *Calculation*—The initial and final angle shall be read to the nearest 0.1° by means of the vernier (Fig. 15) attached to the machine (Note 8).

NOTE 8—See Fig. 16 for sample data and computation sheet for the toughness test.

The toughness shall then be calculated as follows:

$$T = wL(\cos A_2 - \cos A_1) \quad (1)$$

FIG. 11 Hatt-Turner Impact Machine, Illustrating Test Method of Conducting Impact Bending Test

where:

- T = toughness (work per specimen, in. · lbf (Nm),
- w = weight of pendulum, lbf (N),
- L = distance from center of the supporting axis to center of gravity of the pendulum, in. (m),
- A_1 = initial angle (Note 9), degrees, and
- A_2 = final angle the pendulum makes with the vertical after failure of the test specimen, degrees.

NOTE 9—Since friction is compensated for in the machine adjustment, the initial angle may be regarded as exactly 30, 45, or 60°, as the case may be.

11.7 *Weight and Moisture Content*—The specimen shall be weighed immediately before test, and after test a moisture section approximately 2 in. (50 mm) in length shall be cut from the specimen near the failure (see 21.1 and 22.1).

12. Compression Perpendicular to Grain

12.1 *Size of Specimens*—The compression-perpendicular-to-grain tests shall be made on 2 by 2 by 6 in. (50 by 50 by 150 mm) specimens. The actual height, width, and length shall be measured (see 22.2).

12.2 *Loading*—The load shall be applied through a metal bearing plate 2 in. (50 mm) in width, placed across the upper surface of the specimen at equal distances from the ends and at right angles to the length (Fig. 17). The actual width of the bearing plate shall be measured (see 22.2).

12.3 *Placement of Growth Rings*—The specimens shall be placed so that the load will be applied through the bearing plate to a radial surface.

FIG. 12 Sample Drum Record of Impact Bending Test

13.3 *Number of Penetrations*—Two penetrations shall be made on a tangential surface, two on a radial surface, and one on each end. The choice between the two radial and between the two tangential surfaces shall be such as to give a fair average of the piece. The penetrations shall be far enough from the edge to prevent splitting or chipping (Note 11).

NOTE 11—See Fig. 20 for a sample data and computation sheet for hardness test.

13.4 *Speed of Testing*—The load shall be applied continuously throughout the test at a rate of motion of the movable crosshead of 0.25 in. (6 mm/min) (see 22.3).

13.5 *Weight and Moisture Content*—The specimen shall be weighed immediately before the test, and after the test a moisture section approximately 1 in. (25 mm) in length shall be cut (see 21.1 and 22.1).

14. Shear Parallel to Grain

14.1 This section describes one method of making the shear-parallel-to-grain test that has been extensively used and found satisfactory.

14.2 *Size of Specimens*—The shear-parallel-to-grain tests shall be made on a 2 by 2 by 2-½ in. (50 by 50 by 63 mm) specimens notched in accordance with Fig. 21 to produce failure on a 2 by 2 in. (50 by 50 mm) surface. The actual dimensions of the shearing surface shall be measured (see 22.2).

14.3 *Procedure*—Use a shear tool similar to that illustrated in Figs. 22 and 23, providing a ¼ in. (3 mm) offset between the inner edge of the supporting surface and the plane of the adjacent edge of the loading surface. Apply the load to and support the specimen on end-grain surfaces. The shear tool shall include an adjustable crossbar to align the specimen and support the back surface at the base plate. Take care in placing the specimen in the shear tool to see that the crossbar is adjusted, so that the edges of the specimen are vertical and the end rests evenly on the support over the contact area. Observe the maximum load only.

14.4 *Speed of Testing*—The load shall be applied continuously throughout the test at a rate of motion of the movable crosshead of 0.024 in. (0.6 mm)/min (see 22.3).

14.5 *Test Failures*—The failure shall be sketched on the datasheet (Note 12). In all cases where the failure at the base of the specimen extends back onto the supporting surface, the test shall be culled.

NOTE 12—See Fig. 24 for a sample data and computation sheet for the tangential-shear-parallel-to-grain test.

14.6 *Moisture Content*—The portion of the test piece that is sheared off shall be used as a moisture specimen (see 21.1 and 22.1).

15. Cleavage

15.1 *Size of Specimens*—The cleavage tests shall be made on specimens of the form and size in accordance with Fig. 25. The actual width and length at minimum section shall be measured (see 22.2).

12.4 *Speed of Testing*—The load shall be applied continuously throughout the test at a rate of motion of the movable crosshead of 0.012 in. (0.305 mm)/min (see 22.3).

12.5 Load-Compression Curves:

12.5.1 Load-compression curves (Note 10) shall be taken for all specimens up to 0.1 in. (2.5 mm) compression, after which the test shall be discontinued. Compression shall be measured between the loading surfaces.

NOTE 10—See Fig. 18 for a sample compression-perpendicular-to-grain data sheet form.

12.5.2 Deflection readings shall be taken to 0.0001 in. (0.002 mm).

12.6 *Weight and Moisture Content*—The specimen shall be weighed immediately before test, and after test a moisture section approximately 1 in. (25 mm) in length shall be cut adjacent to the part under load (see 21.1 and 22.1).

13. Hardness

13.1 *Size of Specimens*—The hardness tests shall be made on 2 by 2 by 6 in. (50 by 50 by 150 mm) specimens. The actual cross-sectional dimensions and length shall be measured (see 22.2).

13.2 *Procedure*—Use the modified ball test with a “ball” 0.444 in. (11.3 mm) in diameter for determining hardness (Fig. 19). The projected area of the ball on the test specimen is 1 cm². Record the load at which the ball has penetrated to one half its diameter, as determined by an electric circuit indicator or by the tightening of the collar against the specimen.

15.4 Sketch of Failure—The failure shall be sketched on the data sheet (Note 13).

NOTE 13—See Fig. 28 for a sample data and computation sheet for the cleavage test.

15.5 Moisture Content—One of the pieces remaining after failure, or a section split along the surface of failure, shall be used as a moisture specimen (see 21.1 and 22.1).

16. Tension Parallel to Grain

16.1 One test method of determining the tension-parallel-to-grain strength of wood is given in the following procedure.

16.2 Size of Specimens—The tension-parallel-to-grain tests shall be made on specimens of the size and shape in accordance with Fig. 29. The specimen shall be so oriented that the direction of the annual rings at the critical section on the ends
