This document is not an ASTM standard and is intended only to provide the user of an ASTM standard an indication of what changes have been made to the previous version. Because it may not be technically possible to adequately depict all changes accurately, ASTM recommends that users consult prior editions as appropriate. In all cases only the current version of the standard as published by ASTM is to be considered the official document.

Designation:G73-04

## Standard Practice for Liquid Impingement Erosion TestingDesignation: G73 – 10

## Standard Test Method for Liquid Impingement Erosion Using Rotating Apparatus<sup>1</sup>

This standard is issued under the fixed designation G73; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon ( $\varepsilon$ ) indicates an editorial change since the last revision or reapproval.

#### 1. Scope

1.1 This <u>practice\_test method\_covers</u> tests in which solid specimens are eroded or otherwise damaged by repeated discrete impacts of liquid drops or jets. Among the collateral forms of damage considered are degradation of optical properties of window materials, and penetration, separation, or destruction of coatings. The objective of the tests may be to determine the resistance to erosion or other damage of the materials or coatings under test, or to investigate the damage mechanisms and the effect of test variables. Because of the specialized nature of these tests and the desire in many cases to simulate to some degree the expected service environment, the <u>promulgationspecification</u> of a <u>method\_standard apparatus</u> is not deemed practicable. This <u>practicetest method</u> gives guidance in setting up a test, and specifies test and analysis procedures and reporting requirements that can be followed even with quite widely differing materials, test facilities, and test conditions. It also provides a standardized scale of erosion resistance numbers applicable to metals and other structural materials. It serves, to some degree, as a tutorial on liquid impingement erosion.

1.2 The values stated in SI units are to be regarded as standard. The inch-pound units in parentheses are provided for information.

1.3 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

#### 3. Terminology

3.1 See Terminology G40 for definitions of terms that are not defined below in either 3.2 or 3.3.-. Definitions appear in 3.2 quotes definitions, taken from Terminology that are taken from Terminology G40, for important terms related to the title, Scope, or Summary of this practice. for important terms related to the title, Scope, or Summary of this test method. Definitions of Terms Specific to this Test Method are given in 3.3 gives definitions of terms specific to this practice that are not in Terminology that are not in Terminology G40.

3.2 Definitions—All definitions listed below are quoted from Terminology G40-02G40. -05 (some modified).

3.2.1 *cumulative erosion-time curve*, *n*—*in cavitation and impingement erosion*, a plot of cumulative erosion versus cumulative exposure duration, usually determined by periodic interruption of the test and weighing of the specimen. This is the primary record of an erosion test. Most other characteristics, such as the incubation period, maximum erosion rate, terminal erosion rate, and erosion rate-time curve, are derived from it.

3.2.2 *damage*, *n*—*in cavitation or impingement*, any effect on a solid body resulting from its exposure to these phenomena. This may include loss of material, surface deformation, or any other changes in microstructure, properties, or appearance.

3.2.2.1 *Discussion*—This term as here defined should normally be used with the appropriate modifier, for example, "cavitation damage," "liquid impingement damage," "single-impact damage," and so forth.

3.2.3 incubation period, n—in cavitation and impingement erosion, the initial stage of the erosion rate-time pattern during which the erosion rate is zero or negligible compared to later stages. Also, the exposure duration associated with this stage. (Quantitatively it is sometimes defined as the intercept on the time or exposure axis, of a straight line extension of the maximum-slope portion of the cumulative erosion-time curve.), the initial stage of the erosion rate-time pattern during which the erosion rate is zero or negligible compared to later stages.

<u>3.2.3.1 Discussion</u>—The incubation period is usually thought to represent the accumulation of plastic deformation and internal stresses under the surface hat precedes significant material loss. There is no exact measure of the duration of the incubation period. See related term, *nominal incubation period* in 3.3.9.

3.2.4 *liquid impingement erosion*, *n*—progressive loss of original material from a solid surface due to continued exposure to impacts by liquid drops or jets.

3.2.5 maximum erosion rate, n—in cavitation and liquid impingement, the maximum instantaneous erosion rate in a test that exhibits such a maximum followed by decreasing erosion rates. (See also erosion rate-time pattern.)

3.2.5.1 *Discussion*—Occurrence of such a maximum is typical of many cavitation and liquid impingement tests. In some instances it occurs as an instantaneous maximum, in others as a steady-state maximum which persists for some time.

3.2.6 normalized erosion resistance,  $N_{\rm e}$ , *n*—the volume loss rate of a test material, divided into the volume loss rate of a specified reference material similarly tested and similarly analyzed. By "similarly analyzed" is meant that the two erosion rates must be determined for corresponding portions of the erosion rate-time pattern; for instance, the maximum erosion rate or the terminal erosion rate. —a measure of the erosion resistance of a test material relative to that of a specified reference material, calculated by dividing the volume loss rate of the reference material by that of the test material when both are similarly tested and similarly analyzed. By "similarly analyzed" is meant that the two erosion rates must be determined for corresponding portions of the reference material by that of the test material when both are similarly tested and similarly analyzed. By "similarly analyzed" is meant that the two erosion rates must be determined for corresponding portions of the erosion rate or the terminal erosion rate.

3.2.6.1 *Discussion*—A recommended complete wording has the form, "The normalized erosion resistance of (test material) relative to (reference material) based on (criterion of data analysis) is (numerical value)."

3.2.7 normalized incubation resistance,  $N_0$ , *n*—in cavitation and liquid impingement erosion, the <u>nominal</u> incubation period of a test material, divided by the <u>nominal</u> incubation period of a specified reference material similarly tested and similarly analyzed. (See also *normalized erosion resistance*.)

3.3 Definitions of Terms Specific to This Standard:

3.3.1 *apparatus severity factor, F*—an empirical factor that accounts for the systematic differences between rationalized erosion rates (or rationalized incubation periods) as determined for the same material and impact velocity in different facilities. It reflects variations in test conditions not accounted for by the data reduction procedures of this practice. test method.

3.3.2 *erosion resistance number*; NER—the normalized erosion resistance of a test material relative to a standardized scale, calculated from test results with one or more designated reference materials as described in this practice. test method. See also *reference erosion resistance* (3.3.11). (3.3.12).

3.3.3 exposed surface (or area)—that surface (or area) on the specimen nominally subjected to liquid impingement.

(1) For "distributed impact tests," it is generally to be taken as the projected area of the exposed surface of the specimen on a plane perpendicular to the direction of impingement. However, if a plane specimen surface is deliberately oriented so as to obtain impingement at an oblique angle, then the actual plane area is used.

(2) For "repetitive impact tests," it is to be taken as the projected area of the impinging liquid bodies on the specimen, the projection being taken in the direction of relative motion.

3.3.3.1 *Discussion*—In practice, it is usually found that the damaged area in repetitive impact tests is greater than the exposed area as defined above, but the above definition is adopted not only for simplicity but also for consistency between some of the other calculations for distributed and repetitive tests.

# G73 – 10

3.3.4 *impingement rate,*  $U_i$  [LT<sup>-1</sup>]—the volume of liquid impinging per unit time on a unit area of exposed surface; for a plane target surface it is given by  $\psi V \cos \theta$ .

3.3.5 *incubation impingement*,  $H_0$  [L]—the mean cumulative impingement corresponding to the <u>nominal</u> incubation period; hence, impingement rate times <u>nominal</u> incubation time.

3.3.6 *incubation resistance number*, NOR—the normalized incubation resistance of a test material relative to a standardized scale, calculated from test results with one or more designated reference materials as described in this practice. test method. See also reference incubation resistance (3.3.123.3.13).

3.3.7 *incubation specific impacts,*  $N_0$ —same as rationalized incubation period.

3.3.8 *mean cumulative impingement*, H [L]—the cumulative volume of liquid impinged per unit area of exposed surface; impingement rate times exposure time.

#### <del>3.3.9</del>

<u>3.3.9 nominal incubation period</u>,  $t_0$ —the intercept on the time or exposure axis of the straight-line extension of the maximum-slope portion of the cumulative erosion-time curve; while this is not a true measure of the incubation stage, it serves to locate the maximum erosion rate line on the cumulative erosion versus exposure coordinates.

<u>3.3.10</u> rationalized erosion rate,  $R_{\rm e}$ —volume of material lost per unit volume of liquid impinged, both calculated for the same area.

#### 3.3.10

<u>3.3.11</u> rationalized incubation period,  $N_0$ —the duration of the <u>nominal</u> incubation period expressed in dimensionless terms as the number of specific impacts; hence, the specific impact frequency times incubation time. (Also referred to as "incubation specific impacts.")

3.3.113.3.12 reference erosion resistance,  $S_{er}$ —a normalized erosion resistance, based on interlaboratory test results, assigned to a specified reference material in this practicetest method so as to constitute a benchmark in the "erosion resistance number" scale. The value of unity is assigned to 316 stainless steel of hardness 155 to 170 HV.

3.3.12<u>3.3.13</u> reference incubation resistance,  $S_{or}$ —a normalized incubation resistance, based on interlaboratory test results, assigned to a specific reference material in this practice so as to constitute a benchmark in the "incubation resistance number" scale. The value of unity is assigned to 316 stainless steel of hardness 155 to 170 HV.

3.3.13specific impacts, N—the number of impact stress cycles of damaging magnitude experienced by a typical point on the exposed surface, or an approximation thereof as estimated on the basis of simplified assumptions as described in this practice. (This concept has sometimes been termed "impacts per site.") —a normalized incubation resistance, based on interlaboratory test results, assigned to a specific reference material in this test method so as to constitute a benchmark in the "incubation resistance number" scale. The value of unity is assigned to 316 stainless steel of hardness 155 to 170 HV.

3.3.14 <u>specific impacts, N—the number of impact stress cycles of damaging magnitude experienced by a typical point on the exposed surface, or an approximation thereof as estimated on the basis of simplified assumptions as described in this test method. (This concept has sometimes been termed "impacts per site.")</u>

<u>3.3.15</u> specific impact frequency,  $f_i$  [T<sup>-1</sup>]—the number of specific impacts experienced per unit time, given by (*a/b*)  $U_i$ . 3.3.15

<u>3.3.16</u> volume concentration,  $\psi$ —the ratio of the volume of liquid to the total volume in the path traversed or swept out by the exposed area of the specimen.

### 3.3.16

<u>3.3.17</u> *volume mean diameter* [L]—in a population of drops of different sizes, the diameter of a sphere whose volume equals the total volume of all drops divided by the total number of drops.

3.4 Symbols: A

=exposed area of specimen, m

<u>A</u> = <u>exposed area of specimen, m</u><sup>2</sup>, <u>projected</u> <u>projected</u> area of impinging drop or jet, m<sup>2</sup>, <u>bolume</u> volume of impinging drop or jet, m<sup>3</sup>, <u>diameter</u> diameter of impinging drop or jet, m, <u>e</u> <u>apparatus</u> apparatus severity factor for incubation, <u>e</u> <u>apparatus</u> apparatus severity factor for erosion rate,

Ξ
