## Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see [www.iso.org/directives](http://www.iso.org/directives)).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see [www.iso.org/patents](http://www.iso.org/patents)).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see [www.iso.org/iso/foreword.html](http://www.iso.org/iso/foreword.html).

This document was prepared by Technical Committee ISO/TC 206, *Fine ceramics*.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at [www.iso.org/members.html](http://www.iso.org/members.html).

# Fine ceramics (advanced ceramics, advanced technical ceramics) — Test method for determining bonding strength of ceramic coatings

## 1 Scope

This document specifies the testing method for the determination of the bonding strength of ceramic coatings at ambient temperature by the compression tests on the cross-joined test pieces. Methods for test piece preparation, test mode and rate, data collection and reporting procedures are addressed.

This document applies primarily to any ceramic coatings, thick or thin, bonded onto substrates of various materials. The test method described can be used for materials research, quality control, characterization and design data generation purposes.

## 2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO 3611, *Geometrical product specifications (GPS) — Dimensional measuring equipment: Micrometers for external measurements — Design and metrological characteristics*

ISO 7500-1, *Metallic materials — Calibration and verification of static uniaxial testing machines — Part 1: Tension/compression testing machines — Calibration and verification of the force-measuring system*

## 3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

- ISO Online browsing platform: available at <https://www.iso.org/obp>
- IEC Electropedia: available at <http://www.electropedia.org/>

### 3.1 ceramic coating

coating of ceramics onto a substrate, via a physical or chemical technique, which creates an interface or boundary between the coating and the substrate

### 3.2 interface

smooth or rough boundary generated between coating and substrate that results from one or several bonding mechanisms, for example mechanical anchorage, interatomic or intermolecular bonds

### 3.3 cross-joined test piece

test piece prepared by joining coating sample (see [Figure 1](#) and [7.1.1](#)) and coupling bar (see [Figure 2](#) and [7.2.2](#)) perpendicularly to each other at middle, by means of high-strength adhesive, as shown in [Figure 3](#)

$\tau_c$	Shear bonding strength of ceramics coating	MPa	<a href="#">9.2</a>

**5 Principle**

A cross-joined test piece is subjected to an increasing compression load giving a tensile or shear stress on the area that is joined until the coating is debonded. Two different forms of mounting the cross-joined test piece in a fixture are conducted to measure the tensile and shear bond strength, respectively. In the case of the tensile test, a uniaxial tensile stress is generated when the cross-joined test piece is subjected to compressive load, as shown in [Figure 4](#). The tensile strength of the coating–substrate interface, or the cohesive strength of the ceramic coating, will be obtained. In the case of the shear strength test, a cross-joined test piece is loaded in compression to induce failure by shear at the interface, as shown in

Figure 5. Owing to the groove, the failure will not occur in the adhesive interface, and thus the shear bonding strength shall be that of ceramic coating to be characterized. On the other hand, if that coating sample is joined with a flat coupling bar, the adhesive may also lead to the removal of the coating from substrate under shear stress. The test is performed at a constant cross-head displacement rate. The load at fracture and the cross-joined area are used to calculate the tensile and shear bonding strengths by calculation.

ISO 23114:2020

<https://standards.iteh.ai/catalog/standards/sist/25d360be-f076-4667-b1d4-e4f3b3cb7c9/iso-23114-2020>

**Figure 5 — Schematic of loading, supporting and jointed area (dark) for cross-joined test piece in the test of the shear bonding strength**

There are three possible fracture modes during either tensile or shear testing: a) complete removal of the coating from substrate (debonded at the interface between coating and substrate); b) the coating itself fractures (cohesive failure inside the coating); and c) adhesive joint fails. A combination of these three modes can occur. For mode a), the calculated strength value represents the real bonding strength of the coating. For mode b) and mode c), the strength calculated with the failure load and the jointed area shall be lower than the real bonding strength between the coating and the substrate.

## 6 Apparatus

### 6.1 Testing machine

A suitable testing machine capable of applying a uniform cross-head speed shall be used. The testing machine shall be in accordance with ISO 7500-1, Class 1, with an accuracy of 1 % of indicated load at compression or tension tests.

### 6.2 Data acquisition

Obtain an autographic record of the applied load versus cross-head displacement or versus testing time, so that the maximum load to debonding ( $P_c$ ) is determined.
