European foreword

This document (prEN 17149-3:2023) has been prepared by Technical Committee CEN/TC 256 “Railway applications”, the secretariat of which is held by DIN.

This document is currently submitted to the CEN Enquiry.

This document is part of the series EN 17149 *Railway applications — Strength assessment of railway vehicle structures*, which consists of the following parts:

- Part 1: General
- Part 3: Fatigue strength assessment based on cumulative damage

The following part is under preparation:

- Part 2: Static strength assessment

iTeh STANDARD PREVIEW

<https://standards.iteh.ai/catalog/standards/sist/ab6a1f9c-37a6-4766-98ae-0c81f541a40b/osist-pren-17149-3-2023>

Introduction

If a fatigue strength assessment is necessary for rail vehicle structures, this assessment may be made with an endurance limit approach or a cumulative damage approach.

An endurance limit approach is based on the assessment of the stress ranges (e.g. derived from the design load cases or from measurements) against the applicable endurance limit. Such an approach is applicable in combination with the loads given in EN 12663 series or EN 13749.

A fatigue strength assessment based on cumulative damage takes into consideration stress spectra with variable amplitudes and numbers of cycles or stress time histories. This document provides the basic procedure and criteria for a pragmatic method to be applied for fatigue strength assessments based on the cumulative damage approach.

This document does not provide any fatigue strength data, procedures or criteria for an endurance limit approach. The main body of the document is based on the nominal stress approach, but the consideration of variable amplitudes and number of cycles using methods described in this standard may equally be applied with the structural stress and the notch stress approach (additional information for these assessment methods is included as informative annexes).

Within this document the term fatigue strength assessment is always related to the cumulative damage approach unless otherwise noted.

iTeh STANDARD PREVIEW

1 Scope

This document describes a procedure for fatigue strength assessment based on cumulative damage of rail vehicle structures that are manufactured, operated and maintained in accordance with standards valid for rail system applications.

This document is applicable for variable amplitude load data with total number of cycles higher than 10000 cycles.

An endurance limit approach is outside the scope of this document.

The assessment procedure is restricted to ferrous materials and aluminium.

This document does not define design load cases.

This document is not applicable for corrosive conditions or elevated temperature operation in the creep range.

This document is applicable to all kinds of rail vehicles; however it does not define in which cases a fatigue strength assessment using cumulative damage is to be applied.

2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

¹ At draft stage.

4 Stress determination

4.1 General

Fatigue loads acting on a component cause fatigue stresses that can be expressed as a stress spectrum. The stress spectrum used to perform the fatigue strength assessment based on cumulative damage approach shall be expressed in terms of stress ranges, mean stresses and number of cycles to represent the design life.

The design stress spectrum shall incorporate any necessary allowance to account for uncertainties in their values (see 6.2).

NOTE EN 12663 series, EN 15827 and EN 13749 contain information on how to determine design loads for cumulative damage assessment of rail vehicles.

The combination of the individual stress components direct and shear is considered in 7.5.

4.2 Parent material

The stresses for the parent material shall be determined as described in prEN 17149-1:2021, 5.2.

4.3 Welded joints

4.3.1 Modified nominal stresses

The modified nominal stresses for welded joints shall be determined in accordance with prEN 17149-1:2021, 5.3.

4.3.2 Structural stresses and notch stresses

For the fatigue strength assessment of welded joints, the structural stress approaches and the notch stress approach may be applied. For the application of these approaches, the requirements for the calculation of the relevant stresses and fatigue strength are described in the following informative annexes:

- Annex G for the structural stress approach and
- Annex H for the notch stress approach.

5 Fatigue strength

5.1 Parent material

5.1.1 General

This clause describes the method to derive the fatigue strength of parent material under the following conditions:

- materials used such as construction steel, weldable cast steel, cast iron (GJS and ADI), wrought steel, cast aluminium, and wrought aluminium;
- application temperature up to 100 °C for aluminium and up to 200 °C for steel;
- plane stress tensor on the components surface (no significant stress component perpendicular to the surface, e.g. press fit connection).

The restrictions defined above are met with most applications of parent material for rail vehicles, in which case a simplified assessment method is appropriate. If the scope of the application is exceeded, an

assessment method shall be chosen which accounts for the specific application (e.g. high temperatures and 3-dimensional stress states).

Annex C gives an overview over the applicable material factors.

5.1.2 Component fatigue strength $\Delta\sigma_R$ and $\Delta\tau_R$

The fatigue strength is specified by S-N curves, which define the values of the component fatigue strength expressed as stress range $\Delta\sigma_R$ and $\Delta\tau_R$ (in N/mm², unless stated otherwise) related to:

- $N_C = 10^6$,
- stress ratio $R_\sigma = R_\tau = -1$,
- survival probability of $P_s = 97,5\%$,
- membrane stresses.

The values of the component fatigue strength are determined with Formula (1) and Formula (2):

$$\Delta\sigma_R (N_C = 10^6, R_\sigma = -1) = R_m \cdot f_{R,\sigma} \cdot f_{SR,\sigma} \cdot f_{R,C} \quad (1)$$

$$\Delta\tau_R (N_C = 10^6, R_\tau = -1) = R_m \cdot f_{R,\tau} \cdot f_{SR,\tau} \cdot f_{R,C} \quad (2)$$

5.1.3 Material properties

5.1.3.1 Tensile strength in accordance with material standards $R_{m,N}$

$R_{m,N}$ is the nominal tensile strength in accordance with the material standards considering the actual sheet thickness. For machined components, the thickness before machining (semi-finished product) shall be considered.

For rolled sheets and extrusions an anisotropy factor f_A shall be considered in the direction transverse to the main direction of rolling in accordance with Table , unless this is already considered or explicitly excluded in the material standard or component specification. For other material applications $f_A = 1,0$.

$$R_m = f_A \cdot R_{m,N} \quad (3)$$

Table 1 — Anisotropy factor f_A for steel and aluminium

Material	$R_{m,N}$ [N/mm ²]	f_A
Rolled Steel	≤ 600	0,9
	$> 600 \leq 900$	0,86
Rolled sheets and extrusions of aluminium	≤ 200	1,0
	$> 200 \leq 400$	0,95
	$> 400 \leq 600$	0,9
All other material applications	Any value	1,0
Heat-affected zone	Any value	1,0

For heat-affected zones in the vicinity of welded joints the nominal tensile strength for the heat-affected zone $R_{m,HAZ}$ shall be used instead of R_m . The value for $R_{m,HAZ}$ shall be derived from technical literature (e.g. [2], [5], [57], [58]).

5.1.3.2 Tensile strength specified by drawing or specification $R_{m,s}$

As an alternative to a material standard, the mechanical properties may be specified by the drawing or specification.

$R_{m,s}$ is the tensile strength in accordance with a drawing or component specification. If higher values than those defined in the material standards are specified for $R_{m,s}$ and the values are checked only by random testing, then the specified values are not sufficiently reliable and therefore would be non-conservative to use for the purposes of a fatigue strength assessment. To perform a fatigue strength assessment with a survival probability of $P_S = 97,5\%$ the tensile strength $R_{m,s}$ defined by the drawing or component specification shall be reduced in accordance with Formula (4):

$$R_m = f_{R_{m,s}} \cdot R_{m,s} \quad (4)$$

If the strength value is checked by three random tests (e.g. hardness test or tensile test) a value of $f_{R_{m,s}} = 0,94$ is applicable. For other numbers of tests, this value shall be adjusted in accordance with technical literature (e.g. [2]).

If a validated $P_S = 97,5\%$ value within the component is available, $f_{R_{m,s}}$ may be set to 1,0.

NOTE Strength values verified with 3.1 certificate in accordance with EN 10204 are examples for such values.

The $R_{m,N}$ values defined in material standards for a given wall thickness may be used for the purposes of fatigue strength assessment with a survival probability of $P_S = 97,5\%$.

5.1.3.3 Influence of technological size

The assessment method described in this standard does not make any adjustment for the wall thickness of the component. The strength properties used shall consider the appropriate wall thickness.

For components made from semi-finished products the strength properties shall consider the wall thickness of the original semi-finished product.

5.1.3.4 Influence of application temperature

If the component operating temperature remains within the scope of applicability defined by this standard, no further adjustment to account for the application temperature is required for the fatigue strength assessment.

5.1.4 Design Parameters

5.1.4.1 Surface roughness factor f_{SR}

The surface roughness factor f_{SR} is dependent on the material, the nominal tensile strength R_m , the surface roughness R_z and the manufacturing process and is defined by Formula (5) and Formula (6).

$$f_{SR,\sigma} = f_{SR,edge} \cdot \left(1 - a_{R,\sigma} \cdot \log \frac{R_z}{[\mu m]} \cdot \log \frac{2 R_m}{b_R} \right) \quad (5)$$

$$f_{SR,\tau} = f_{SR,edge} \cdot \left(1 - f_{R,\tau} \cdot a_{R,\sigma} \cdot \log \frac{R_z}{[\mu m]} \cdot \log \frac{2 R_m}{b_R} \right) \quad (6)$$

$a_{R,\sigma}$ und b_R are given in Table 2. $f_{R,\tau}$ is given in Table 4.

Table 2 — Factors $a_{R\sigma}$ and b_R for steel and aluminium

Material	$a_{R,\sigma}$	b_R [N/mm ²]
Steel (rolled or forged)	0,22	400
Steel castings	0,20	400
Spheroidal graphite cast iron (GJS)	0,16	400
Ausferritic spheroidal graphite cast iron (ADI)	0,16	400
Aluminium	0,22	133
Cast aluminium	0,20	133

Typical values of the surface roughness R_Z are given in Table 3. The factor $f_{SR,edge}$ accounts for the effect of thermal cut edges of steel.

Table 3 — Typical values for R_Z , R_a and $f_{SR,edge}$

R_Z [μm]	R_a [μm]	$f_{SR,edge}$	Example
a	a	1,0	Plate surface or machined edge of steel
80 ^a	25 ^a	1,0	Shot blasted rolled sheet surface; Rolled sheet and extrusions of aluminium
200 ^a	50 ^a	1,0	Rolled sheet surface of steel, not shot blasted; Forging steel; Cast surface
50 ^a	12,5 ^a	0,81	thermal flame cutting of steel, shot blasted
200 ^a	50 ^a	0,81	thermal flame cutting of steel, not shot blasted
25 ^a	6,3 ^a	0,94	Plasma or laser cut plate edges of steel, shot blasted
200 ^a	50 ^a	0,94	Plasma or laser cut plate edges of steel, not shot blasted
200	50	1,0	Plasma or laser cut plate edges of aluminium, not shot blasted. (An improvement in the surface roughness factor is only applicable if the affected material (typically 2 mm) is completely removed by machining after cutting.)

a If explicit values for surface roughness are defined in the drawing or component specification those values shall be used for the fatigue strength assessment. When applied to castings the benefit of machined surfaces is only applicable if the machined surface is free from surface breaking defects.

For plate edges of rolled sheets the following requirements shall be applied:

- Sharp corners and surface rolling flaws shall be removed by longitudinal grinding or during subsequent manufacturing processes, for example shot blasting;
- cracks or visible gouges are not permitted;
- weld repairs shall be treated as welded joints;
- notch effects due to shape of edges shall be considered;

- minimum corner radius or chamfer 1 mm;
- all burrs shall be removed.

For plate edges of steel manufactured by plasma and laser cut the surface roughness factor for cut edges $f_{SR,edge}$ shall be applied in accordance with Table 3.

For plate edges of aluminium, manufactured by plasma or laser cut a surface roughness of $R_z = 200 \mu\text{m}$ shall be applied independent of the actual surface roughness to account for the local metallurgical effects. An improvement in the surface roughness factor is only applicable if the affected material (typically 2 mm) is completely removed by machining after cutting.

The values are valid for nominal stress without the consideration of any stress gradients perpendicular to the surface. In the case of a stress gradient perpendicular to the surface (e.g. stress concentration) the influence of the surface roughness may be reduced in accordance with technical literature, e.g. [2].

5.1.4.2 Influence of stress gradient

In the assessment method described in this standard the benefit for the fatigue strength associated with the stress gradient perpendicular to the surface is not included in the fatigue strength values.

The beneficial effects of stress gradients may be considered in accordance with technical literature, e.g. [2].

5.1.4.3 Influence of surface treatment

As a conservative approach in this simplified assessment method the benefit for the fatigue strength associated with the surface treatment (e.g. peening) is not included.

The beneficial effects of the surface treatment may be considered in accordance with technical literature, e.g. [2].

5.1.5 Fatigue strength factors for direct stresses $f_{R,\sigma}$ and for shear stresses $f_{R,\tau}$

For the determination of the component fatigue strength (stress range) for parent material the fatigue strength factors given in Table 4 shall be used. These fatigue strength factors are related to $N_C = 10^6$ cycles and a stress ratio of $R = -1$ and correspond to a survival probability of $P_S = 97,5 \%$.

Table 4 — Fatigue strength factors for direct stresses and shear stresses related to $N_C = 10^6$ cycles

Material	$f_{R,\sigma}$	$f_{R,\tau}^a$
Steel (rolled or forged)	0,75	0,577
Steel castings	0,57	0,577
Spheroidal graphite cast iron (GJS)	$0,42 + \frac{117 \text{ N/mm}^2}{R_m}$	0,65
Ausferritic spheroidal graphite cast iron (ADI)	$\frac{492 \text{ N/mm}^2}{R_m}$	0,7
Aluminium	0,6	0,577
Cast aluminium	0,6	0,75
^a Ratio between the fatigue strength of shear stress and the one of direct stress.		

NOTE For steel castings and spheroidal graphite cast iron, the fatigue strength factors $f_{R,\sigma}$ given in Table 4 are derived in accordance with [2] (fatigue strength factor for alternating direct stresses $f_{w,\sigma}$). The fatigue strength

factors represent the fatigue strength ratio with respect to stress range, these factors include a margin of 1,2 as given in [2] to cover uncertainties. For aluminium, the fatigue strength factors given in Table 4 are determined in accordance with test results.

5.1.6 Correction factor for casting $f_{R,C}$

The NDT-level and the corresponding casting quality level applied for castings have an influence on the fatigue strength values for the cast component. The correction factor for casting $f_{R,C}$ accounts for the effects of any remaining defects on the fatigue strength within the casting component. For all non-cast components $f_{R,C} = 1,0$.

In the case of structural castings, it is necessary to specify the quality requirements with respect to the permitted volumetric and surface defect levels to guarantee the mechanical properties to be achieved in regions subjected to high stresses. The relevant mechanical properties and quality requirements shall be verified in accordance with the component specification.

The correction factor for casting $f_{R,C}$ shall be chosen in accordance with the casting quality achieved in the cast component. The values given in Table 5 may be used for castings depending on the NDT-level during production and the verified quality level in accordance with Annex B.

Table 5 — Correction factor for casting $f_{R,C}$

Volumetric inspection by NDT		Inspection of surface conditions		Correction factor for castings $f_{R,C}$
Relevant Standard	Quality level in accordance with ASTM	Relevant standard	Quality class	
EN 12680 (UT) EN 12681 (RT)	Level 3	EN 1369	LM3, AM3, SM4	0,8
		EN 1370	4S1/5S2, VC3	
		EN 1371-1	LP3, AP3 SP3/CP3	
	Level 2	EN 1369	LM2, AM2 SM2	0,9
		EN 1370	3S1/3S2, VC2	
		EN 1371-1	LP2, AP2 SP2/CP2	

The specification of castings needs to ensure appropriate cast quality to maintain the applicability of the assessment method defined in this document. Informative Annex B gives an example for the casting specification requirements related to volumetric quality levels.

An enhancement of the correction factor $f_{R,C}$ up to 1,0 is applicable, if the fatigue strength values within the component are proven by corresponding tests with test specimen from these regions of the component and corresponding quality assurance measures for the manufacturing process.

A strength assessment method that does not consider the internal casting defects (e.g. voids) in components during the stress determination (e.g. a FEA model representing nominal geometry) should be restricted to castings of quality level 3 or better. For components or parts of components that are not stressed significantly inferior quality levels also may be applied.

For an assessment of such castings it should be considered that bigger defects can affect significantly the actual stress distributions (e.g. due to locally reduced sections). Therefore, these effects should either be considered for the determination of the stress distribution or the correction factor for castings $f_{R,C}$ should be reduced accordingly.

5.1.7 S-N curves and methods of cumulative damage rule

For S-N curves of parent material all relevant information is given in Table 6 and Table 7.

Table 6 — Parameters for S-N curves

Cumulative damage rule	Exponent beyond knee point N_D	Cut-off limit $\Delta\sigma_L$	Damage sum limit $D_{m,min}$
Modified version of Miner's rule	$2m-1^a$	$0,5 \Delta\sigma_D$	1,0 for spheroidal graphite cast iron, (GJS, ADI), 0,3 for all other materials
Consistent version of Miner's rule	m_2 for austenitic steel and aluminium	-	1,0 for spheroidal graphite cast iron, (GJS, ADI), 0,3 for all other materials

a No specific symbol is assigned to the exponent beyond the knee point N_D , the slope is defined only by the formula above.

In Figure 1, the principal representation of S-N curves are given for parent material for direct stress. For S-N-curves of shear stresses the symbol σ is replaced by symbol τ .

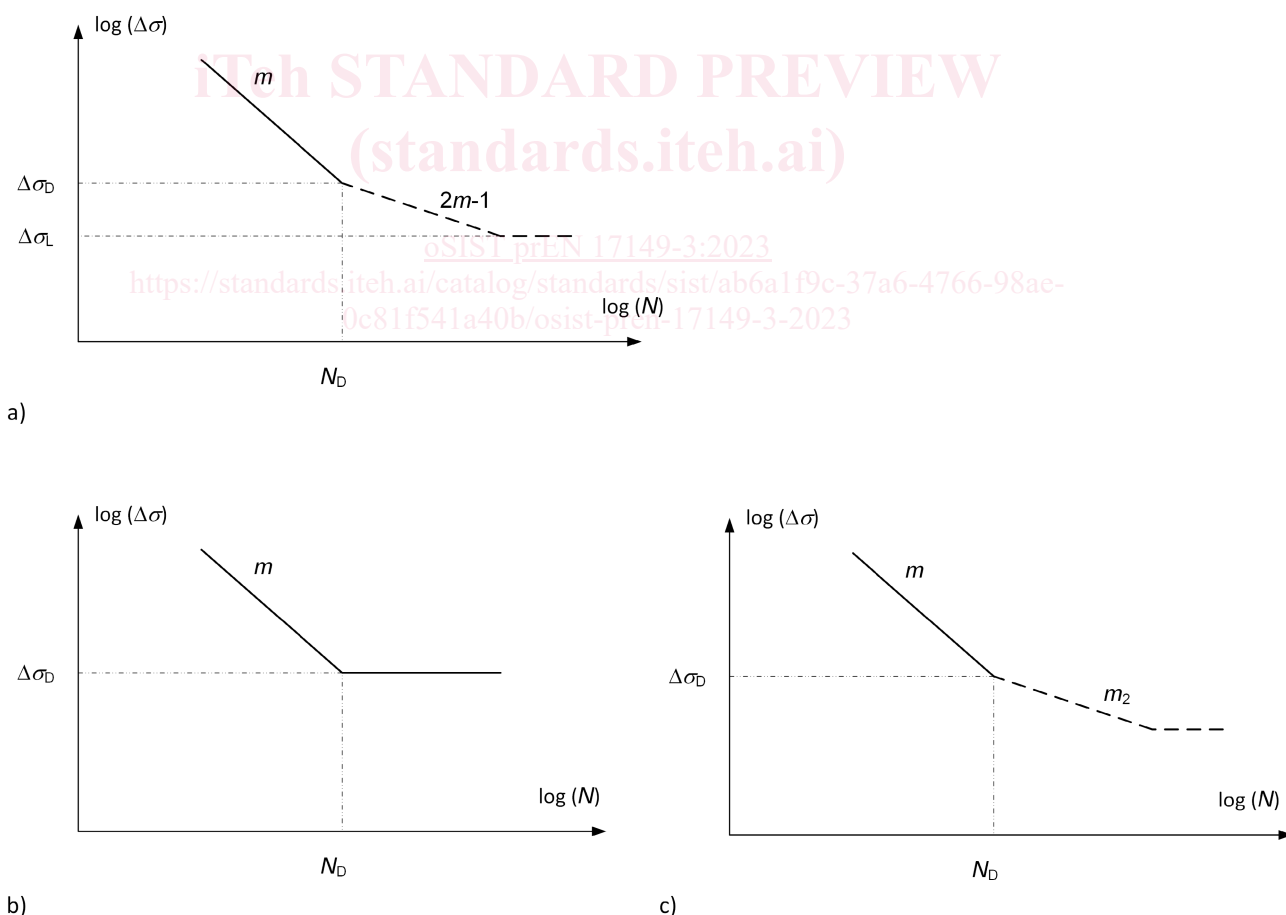

Figure 1 — S-N curves for parent material for direct stresses: a) Miner modified; b) Miner consistent for ferritic steel, steel castings and spheroidal graphite cast iron; c) Miner consistent for austenitic steel and aluminium
