INTERNATIONAL ELECTROTECHNICAL COMMISSION

OPTICAL FIBRES –

**Part 1-41: Measurement methods and test procedures –
Bandwidth**

FOREWORD

- 1) The International Electrotechnical Commission (IEC) is a worldwide organization for standardization comprising all national electrotechnical committees (IEC National Committees). The object of IEC is to promote international co-operation on all questions concerning standardization in the electrical and electronic fields. To this end and in addition to other activities, IEC publishes International Standards, Technical Specifications, Technical Reports, Publicly Available Specifications (PAS) and Guides (hereafter referred to as “IEC Publication(s)”). Their preparation is entrusted to technical committees; any IEC National Committee interested in the subject dealt with may participate in this preparatory work. International, governmental and non-governmental organizations liaising with the IEC also participate in this preparation. IEC collaborates closely with the International Organization for Standardization (ISO) in accordance with conditions determined by agreement between the two organizations.
- 2) The formal decisions or agreements of IEC on technical matters express, as nearly as possible, an international consensus of opinion on the relevant subjects since each technical committee has representation from all interested IEC National Committees.
- 3) IEC Publications have the form of recommendations for international use and are accepted by IEC National Committees in that sense. While all reasonable efforts are made to ensure that the technical content of IEC Publications is accurate, IEC cannot be held responsible for the way in which they are used or for any misinterpretation by any end user.
- 4) In order to promote international uniformity, IEC National Committees undertake to apply IEC Publications transparently to the maximum extent possible in their national and regional publications. Any divergence between any IEC Publication and the corresponding national or regional publication shall be clearly indicated in the latter.
- 5) IEC itself does not provide any attestation of conformity. Independent certification bodies provide conformity assessment services and, in some areas, access to IEC marks of conformity. IEC is not responsible for any services carried out by independent certification bodies.
- 6) All users should ensure that they have the latest edition of this publication.
- 7) No liability shall attach to IEC or its directors, employees, servants or agents including individual experts and members of its technical committees and IEC National Committees for any personal injury, property damage or other damage of any nature whatsoever, whether direct or indirect, or for costs (including legal fees) and expenses arising out of the publication, use of, or reliance upon, this IEC Publication or any other IEC Publications.
- 8) Attention is drawn to the Normative references cited in this publication. Use of the referenced publications is indispensable for the correct application of this publication.
- 9) Attention is drawn to the possibility that some of the elements of this IEC Publication may be the subject of patent rights. IEC shall not be held responsible for identifying any or all such patent rights.

International Standard IEC 60793-1-41 has been prepared by subcommittee 86A: Fibres and cables, of IEC technical committee 86: Fibre optics.

This fourth edition cancels and replaces the third edition published in 2010. This edition constitutes a technical revision.

The main change with respect to the previous edition is the addition of a “direct reference” for method A and method B third method for determining modal bandwidth based on DMD data and to improve measurement procedures for A4 fibres.

This standard should be read in conjunction with IEC 60793-1-1 and IEC 60793-1-2, which cover generic specifications.

118 The text of this standard is based on the following documents:

FDIS	Report on voting
86A/1294/CDV	86A/1329/RVD

119

120 Full information on the voting for the approval of this standard can be found in the report on
121 voting indicated in the above table.

122 This publication has been drafted in accordance with the ISO/IEC Directives, Part 2.

123 A list of all parts of the IEC 60793-1-4x series, published under the general title *Optical fibres*
124 – *measurement methods and test procedures*, can be found on the IEC website

125 The committee has decided that the contents of this publication will remain unchanged until the
126 stability date indicated on the IEC web site under "http://webstore.iec.ch" in the data related to
127 the specific publication. At this date, the publication will be

- 128 • reconfirmed,
- 129 • withdrawn,
- 130 • replaced by a revised edition, or
- 131 • amended.

132

OPTICAL FIBRES –

Part 1-41: Measurement methods and test procedures – Bandwidth

143 1 Scope

144 This part of IEC 60793 describes three methods for determining and measuring the modal
145 bandwidth of multimode optical fibres (see IEC 60793-2-10, IEC 60793-2-30 and IEC 60793-2-
146 40 series). The baseband frequency response is directly measured in the frequency domain by
147 determining the fibre response to a sinusoidally modulated light source. The baseband response
148 can also be measured by observing the broadening of a narrow pulse of light. The calculated
149 response is determined using differential mode delay (DMD) data. The three methods are:

- 150 • Method A – Time domain (pulse distortion) measurement
- 151 • Method B – Frequency-domain measurement
- 152 • Method C – Overfilled launch modal bandwidth calculated from differential mode delay
153 (OMBc)

154 Methods A and B can be performed using one of two launches: an overfilled launch (OFL)
155 condition or a restricted mode launch (RML) condition. Method C is only defined for A1-OM3 to
156 A1-OM5 multimode fibres and uses a weighted summation of DMD launch responses with the
157 weights corresponding to an overfilled launch condition. The relevant test method and launch
158 condition should be chosen according to the type of fibre.

159 NOTE 1 These test methods are commonly used in production and research facilities and are not easily
160 accomplished in the field.

161 NOTE 2 OFL has been used for the modal bandwidth value for LED-based applications for many years. However,
162 no single launch condition is representative of the laser (e.g. VCSEL) sources that are used for gigabit and higher
163 rate transmission. This fact drove the development of IEC 60793-1-49 for determining the effective modal bandwidth
164 of laser optimized 50 µm fibres. See IEC 60793-2-10:2019 or later and IEC 61280-4-1:2019 or later for more
165 information.

166 2 Normative references

167 The following referenced documents are indispensable for the application of this document. For
168 dated references, only the edition cited applies. For undated references, the latest edition of
169 the referenced document (including any amendments) applies.

177 *Differential mode delay*

178 3 Terms and definitions

179 For the purposes of this document, the following terms and definitions apply.

180 3.1

181 bandwidth (–3 dB)

182 value numerically equal to the lowest modulation frequency at which the magnitude of the
183 baseband transfer function of an optical fibre decreases to a specified fraction, generally to one
184 half, of the zero frequency value. The bandwidth is denoted in this document as $f_{3\text{ dB}}$.

185 NOTE It is known that there can be various calculations, sometimes called markdowns, to avoid reporting extremely
186 high values associated with “plateaus”. For example the 1,5 dB frequency, multiplied by $\sqrt{2}$ is one treatment used
187 in IEC 60793-1-49. If such a calculation is used it should clearly be reported.

188 3.2

189 transfer function

190 discrete function of complex numbers, dependent on frequency, representing the frequency-
191 domain response of the fibre under test

192 NOTE Method A determines the frequency response by processing time domain data through Fourier transforms.
193 Method B can only measure the transfer function if an instrument which measures phase as well as amplitude is
194 used. Method C is similar to Method A as it uses Fourier transforms in a similar manner. The transfer Function is
195 denoted in this document as $H(f)$.

196 3.3

197 power spectrum

198 discrete function of real numbers, dependent on frequency, representing the amplitude of the
199 frequency-domain response of the fibre under test

200 NOTE Methods A and C determine the power spectrum from the transfer function. Method B determines the transfer
201 function by taking the ratio of the amplitude measured through the fibre under test and the reference. The power
202 spectrum is denoted in this document as $|H(f)|$.

203 3.4

204 impulse response

205 discrete function of real numbers, dependent on time, representing the time-domain response
206 of the fibre under test to a perfect impulse stimulus. The impulse response is derived, in all
207 methods, through the inverse Fourier transform of the transfer function. The impulse response
208 is denoted in this document as $h(t)$.

209 4 Apparatus

210 4.1 Radiation source

211 4.1.1 Method A – Time domain (pulse distortion) measurement

212 Use a radiation source such as an injection laser diode that produces short duration, narrow
213 spectral width pulses for the purposes of the measurement. The pulse distortion measurement
214 method requires the capability to switch the energy of the light sources electrically or optically.
215 Some light sources shall be electrically triggered to produce a pulse; in this case a means shall
216 be provided to produce triggering pulses. An electrical function generator or equivalent can be
217 used for this purpose. Its output should be used to both induce pulsing in the light source and
218 to trigger the recording system. Other light sources may self-trigger; in this case, means shall
219 be provided to synchronize the recording system with the pulses coming from the light source.
220 This may be accomplished in some cases electrically; in other cases optoelectronic means may
221 be employed.

222 4.1.2 Method B – Frequency domain measurement

223 Use a radiation source such as a continuous wave (CW) injection laser diode for the purposes
224 of the measurement. The frequency domain measurement method requires the capability to
225 modulate the energy of the light sources electrically or optically. Connect the modulation output
226 of the tracking generator or network analyzer through any required driving amplifiers to the
227 modulator.

228 4.1.3 Method C – Overfilled launch modal bandwidth calculated from differential 229 mode delay (OMBc)

230 Use a radiation source as described in IEC 60793-1-49.

231 4.1.4 For methods A and B

232 Annex A Use a radiation source with a centre wavelength that is known and within ± 10 nm of
233 the nominal specified wavelength. For injection laser diodes, laser emission coupled into the
234 fibre shall exceed spontaneous emission by a minimum of 15 dB (optical).

235 Annex B Use a source with sufficiently narrow linewidth to assure the measured bandwidth is
236 at least 90 % of the intermodal bandwidth. This is accomplished by calculating the normalized
237 intermodal dispersion limit, NIDL (refer to Annex A). For A4 fibre, the linewidth of any laser
238 diode is narrow enough to neglect its contribution to bandwidth measurement.

239 Annex C For A1 and A3 fibres, calculate the NIDL (see Annex A) for each wavelength's
240 measurement from the optical source spectral width for that wavelength as follows:

$$241 \text{NIDL} = \frac{\text{IDF}}{\Delta\lambda}, \text{ in GHz}\cdot\text{km}$$

242 where:

243 $\Delta\lambda$ is the source Full Width Half Maximum (FWHM) spectral width in nm,

244 IDF is the Intramodal Dispersion Factor (GHz·km·nm) from Annex A according to the
245 wavelength of the source.

246 NIDL is not defined for wavelengths from 1 200 nm to 1 400 nm. The source spectral
247 width for these wavelengths shall be less than or equal to 10 nm, FWHM.

248 NOTE The acceptability of a NIDL value depends upon the specific user's test requirements. For example, a
249 0,5 GHz·km NIDL would be satisfactory for checking that fibres had minimum bandwidths greater than some value
250 less than 500 MHz·km, but would not be satisfactory for checking that fibres had minimum bandwidths greater than
251 500 MHz·km. If the NIDL is too low, a source with smaller spectral width is required.

252 Annex D The radiation source shall be spectrally stable throughout the duration of a single
253 pulse and over the time during which the measurement is made.

254 4.2 Launch system

255 4.2.1 Overfilled launch (OFL)

256 4.2.1.1 OFL condition for A1 fibre

257 Use a mode scrambler between the light source and the test sample to produce a controlled
258 launch irrespective of the radiation properties of the light source. The output of the mode
259 scrambler shall be coupled to the input end of the test sample in accordance with Annex D. The
260 fibre position shall be stable for the complete duration of the measurement. A viewing system
261 may be used to aid fibre alignment where optical imaging is used.

262 The OFL prescription in Annex D, based on the allowed variance of light intensity on the input
263 of the fibre under test, can result in large (>25 %) variations in the measured results for high
264 bandwidth (>1 500 MHz·km) A1-OM3, A1-OM4 and A1-OM5 fibres. Subtle differences in the
265 launches of conforming equipment are a cause of these differences. Method C is introduced as
266 a means of obtaining an improvement.

267 Provide means to remove cladding light from the test sample. Often the fibre coating is sufficient
268 to perform this function. Otherwise, it will be necessary to use cladding mode strippers near
269 both ends of the test sample. The fibres may be retained on the cladding mode strippers with
270 small weights, but care shall be taken to avoid microbending at these sites.

271 NOTE Bandwidth measurements obtained by the overfilled launch (OFL) support the use of category A1 multimode
272 fibres, especially in LED applications at 850 nm and 1 300 nm. Some laser applications may also be supported with
273 this launch, but could result in reduced link lengths (at 850 nm) or restrictions on the laser sources (at 1 300 nm).

274 4.2.1.2 OFL condition for A3 and A4 fibres

275 OFL is obtained with geometrical optic launch in which the maximum theoretical numerical
276 aperture of the fibre is exceeded by the launching cone and in which the diameter of the
277 launched spot is in the order of the core diameter of the fibre. The light source shall be able to
278 excite both low-order and high-order modes in the fibre equally.

279 NOTE A mode scrambler excites more or less all modes. Mode excitation is very sensitive to the source/mode
280 scrambler alignment and the interaction with any intermediary optics such as connectors or optical imaging systems.
281 A light source with large NA and core diameter will only excite meridional modes or LP_{0,m} modes.

282 4.2.2 Restricted mode launch (RML)

283 4.2.2.1 RML condition for A1-OM1 fibre

284 The RML for bandwidth is created by filtering the overfilled launch (as defined by Annex D) with
285 a RML fibre. The OFL is defined by Annex D and it needs to be only large enough to overfill the
286 RML fibre both angularly and spatially. The RML fibre has a core diameter of $23,5 \mu\text{m} \pm 0,1 \mu\text{m}$,
287 and a numerical aperture of $0,208 \pm 0,01$. The fibre shall have a graded-index profile with an
288 alpha of approximately 2 and an OFL bandwidth greater than $700 \text{ MHz}\cdot\text{km}$ at 850 nm and 1 300
289 nm. For convenience, the clad diameter should be $125 \mu\text{m}$. The RML fibre should be at least
290 1,5 m in length to eliminate leaky modes; and it should be less than 5 m in length to avoid
291 transient loss effects. The launch exiting the RML fibre is then coupled into the fibre under test.

292 Provide means to remove cladding light from the test sample. Often the fibre coating is sufficient
293 to perform this function. Otherwise, it will be necessary to use cladding mode strippers near
294 both ends of the test sample. The fibres may be retained on the cladding mode strippers with
295 small weights, but care shall be taken to avoid microbending at these sites.

296 NOTE 1 In order to achieve the highest accuracy, tight tolerances are required on the geometry and profile of the
297 RML fibre. In order to achieve the highest measurement reproducibility, tight alignment tolerances are required in
298 the connection between the launch RML fibre and the fibre under test to ensure the RML fibre is centred to the fibre
299 under test.

300 NOTE 2 Bandwidth measurements obtained by a restricted mode launch (RML) are used to support 1 Gigabit
301 Ethernet laser launch applications. The present launch is especially proven for 850 nm sources transported over type
302 A1-OM1 fibres.

303 4.2.2.2 RML condition for A3 fibre

304 RML condition for A3 fibre is created with geometrical optic launch which corresponds to launch
305 $\text{NA} = 0,3$.

306 Spot size shall be larger or equal to the size of core.

307 4.2.2.3 RML condition for A4 fibre

308 The RML for A4 fibre shall correspond to $\text{NA} = 0,3$. It can be created by filtering the overfilled
309 launch with a mandrel wrapped mode filter, shown in Figure 1. The mode filter shall be made
310 with the fibre of the same category as the fibre under test. In order to avoid redundant loss, the
311 length of fibre should be 1 m. The diameter of the mandrel should be 20 times as large as that
312 of the fibre cladding and the number of coils may be 5.

313 NOTE Do not apply any excessive stress in winding fibre on to the mandrel. The wound fibre may be fixed to the
314 mandrel with an adhesive. Unwound parts of fibre should be set straight.

315
316

Figure 1 – Mandrel wrapped mode filter

317 4.2.3 Differential mode delay (DMD) launch

318 The DMD launch shall comply with the launch requirements of IEC 60793-1-49.

319 4.3 Detection system

320 The output optical detection apparatus shall be capable of coupling all guided modes from the
321 test sample to the detector active area such that the detection sensitivity is not significantly
322 mode-dependent.

323 A device shall be available to position the specimen output end with sufficient stability and
324 reproducibility to meet the conditions of 4.6 below.

325 An optical detector shall be used that is suitable for use at the test wavelength, linear in
326 amplitude response, spatially uniform to within 10 %, and sufficiently large to detect all emitted
327 power. An optical attenuator may be used to control the optical intensity on the detector. It shall
328 be mode-independent as well.

329 The detection electronics as well as any signal preamplifier shall be linear in amplitude
330 response (nonlinearities less than 5 %) over the range of encountered signals.

331 The detection system for Method C shall comply with the requirements of IEC 60793-1-49.

332 4.4 Recording system

333 For the time domain (pulse distortion) measurement (method A), use an oscilloscope suitably
334 connected to a recording device, such as a digital processor, to store the received pulse
335 amplitude as a function of time. For temporal measurements, data taken from the oscilloscope
336 display shall be considered secondary to those derived from the recorded signal.

337 For the frequency domain measurement (method B), use a tracking generator-electrical
338 spectrum analyzer combination, scalar network analyzer, vector network analyzer or an
339 equivalent instrument to detect, display and record the amplitude of the RF modulation signal
340 derived from the optical detector. This shall be done in such a manner as to reduce harmonic
341 distortion to less than 5 %.

342 The recording system for Method C shall comply with the requirements of IEC 60793-1-49.

343 4.5 Computational equipment

344 For the time domain (pulse distortion) method (method A) and overfilled launch bandwidth
345 calculated from differential mode delay (method C) or if impulse response is required from
346 method B, computational equipment capable of performing Fourier transforms on the detected
347 optical pulse waveforms as recorded by the waveform recording system shall be used. This
