## Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see [www.iso.org/directives](http://www.iso.org/directives)).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see [www.iso.org/patents](http://www.iso.org/patents)).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see [www.iso.org/iso/foreword.html](http://www.iso.org/iso/foreword.html).

This document was prepared by Technical Committee ISO/TC 130, *Graphic technology*.

This second edition cancels and replaces the first edition (ISO 12647-8:2012), which has been technically revised.

The main changes compared to the previous edition are as follows:

- CIE 1976  $\Delta E^*_{ab}$  has been replaced with modern  $\Delta E_{00}$  colour difference formulae;
- a better metric for uniformity assessment, namely the measurement of 1D distortions of macroscopic uniformity utilizing scanning spectrophotometers, has been added;
- a more content oriented control wedge has been added;
- a new [Annex A](#) has been added to align the content with ISO 12647-7, with respect to substrate categorisation and conformance assessment;
- informative metrics that proved to be not practical, such as tonality, have been deleted.

A list of all parts in the ISO 12647 series can be found on the ISO website.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at [www.iso.org/members.html](http://www.iso.org/members.html).

## Introduction

This document specifies the properties, and associated test methods, required for digital prints and printing processes to meet the criteria established for “validation prints”.

In most printing workflows, there is a requirement for a visual representation of the expected appearance of the document being printed that can be used as part of the agreement between customer and printer. Where this visual representation is produced such that its characteristics (colour fidelity, tone reproduction, registration, size, etc.) simulate those of the expected printing within tight tolerances, it is usually referred to as a “contract proof”. As the name implies, contract proofs are used as part of the contractual relationship between customer and printer and are used as a visual aim for the press operator during printing as well as the absolute reference against which the finished production is compared. Not unexpectedly, systems that can produce contract proofs are usually expensive and require careful operation and maintenance. ISO 12647-7 specifies the requirements for contract proofs and systems used to produce contract proofs directly from digital data.

Recently, other visualizations of the final printed product have found a place in the printing/proofing workflow because designers and print buyers prefer not to go to the expense of using an ISO 12647-7 compliant contract proof any earlier in the process than necessary. In many situations, participants in the workflow require a hardcopy visual reference of lesser quality than a contract proof. In the past, those prints varied widely in quality and were often referred to as design proofs, concept proofs, layout prints, etc. That quality level is here being referred to as a “validation print”.

Because data are exchanged electronically, and visualizations of those data are produced at multiple sites, there is a requirement for defined requirements for validation prints to allow a degree of consistency throughout the workflow. One of the goals of having less stringent requirements, particularly on colour fidelity, is to allow the production of validation prints on less elaborate and less costly devices than are required for contract proofs. The requirements for validation prints and the systems used to produce validation prints are given in this document.

Validation prints are not intended to replace “contract proofs” for predicting colour on production printing devices. It is expected that the modifications of the requirements for validation prints, along with the requirements for contract proofs, will continue in the future as industry requirements and imaging technologies develop.

# Graphic technology — Process control for the production of half-tone colour separations, proof and production prints —

## Part 8:

## Validation print processes working directly from digital data

**IMPORTANT** — This document contains colours which are considered to be useful for the correct understanding of the document. Users should therefore consider printing this document using a colour printer.

### 1 Scope

This document specifies requirements that can be used for determining the conformance of systems that produce a hard-copy validation print, directly from digital data, which is intended to simulate the expected appearance of material printed in accordance with a characterized printing condition.

It is not intended for use in determining the conformance of production printing systems (digital or conventional) since many aspects of production printing are not covered in this document.

### 2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO 187, *Paper, board and pulps — Standard atmosphere for conditioning and testing and procedure for monitoring the atmosphere and conditioning of samples*

ISO 2813, *Paints and varnishes — Determination of gloss value at 20°, 60° and 85°*

### 3 Terms and definitions

For the purposes of this document, the terms and definitions given in ISO 12647-1 and the following apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

- ISO Online browsing platform: available at <https://www.iso.org/obp>
- IEC Electropedia: available at <http://www.electropedia.org/>

#### 3.1

##### **validation print substrate**

substrate used for validation print processes, usually characterized by its light fastness or permanence properties, with only essential requirements dictated by the printing process

#### 3.2

##### **print stabilization period**

time after which the print is chemically and physically stable

Note 1 to entry: It is necessary that this property of the validation print system be specified by the manufacturer. It is most important that the print is stable with respect to colour changes.

#### 3.3

##### **validation print**

print produced directly from digital data early in the production chain following this document, representative of the concept for the final product

Note 1 to entry: A validation print can have reduced accuracy compared to contract proof.

#### 3.4

##### **production substrate**

substrate to be used for production printing, including a substrate originally intended for the validation printing press under test

Note 1 to entry: A production substrate can be a paper with an ink receiving layer or a paper optimized for electrophotographic printing.

### 3.5

#### PDF/X

title of a series of ISO standards regarding the use of the Portable Document Format (PDF) for the dissemination of digital data intended for print reproduction

## 4 Requirements

### 4.1 Data requirements for validation print systems

Validation print systems shall accept digital data delivered as PDF/X data files in accordance with one of the conformance levels defined in ISO 15930-1, ISO 15930-4, ISO 15930-6, ISO 15930-7, ISO 15930-8 or ISO 15930-9. Where the digital data is delivered as PDF/X data files, the intended printing condition being simulated shall be that defined in the OutputIntents array of the PDF/X file. Where a profile is required for data conversion, the profile that is the value of the *DestOutputProfile* key in the PDF/X file shall be used. In case of multi primary based printing conditions (e.g. 5C, 6C, 7C or 8C), data should be delivered as PDF/X-5n. Since this is currently not industrial common, the sender and receiver shall agree on the pertinent data exchange.

NOTE There are a number of industry test suites for testing PDF/X conformance such as The Ghent PDF Output Suite 4,0 or 5,0<sup>[21]</sup> or the Altona Test Suite<sup>[23]</sup>.

### 4.2 Validation print

#### 4.2.1 Validation print substrate qualification

In an ideal situation, the validation print substrate should be the same as the production substrate. As this ideal situation is seldom possible, the following criteria apply for the validation print substrate.

- a) The gloss level of both the printing substrate and validation print substrate should be estimated as one of matte, semi-matte or gloss either by the substrate manufacturer or by measuring as described in 5.6. Matte substrates should not be used to make validation prints for gloss printing substrates and gloss substrates should not be used to make validation prints for matte printing substrates.
- b) The white point of the unprinted validation print substrate shall allow a colorimetric match of the substrate of the intended printing condition to be simulated with a colour difference of less than or equal to  $3,0 \Delta E_{00}$  units when measured according to ISO 13655.

To assure a white point match, the validation print substrate should have a CIE L\* value that is higher than the substrate of the printing condition to be simulated.

- c) The validation print substrate should belong to the same fluorescence classification as the production substrate. Fluorescence classification in four levels of faint, low, moderate, and high shall be made in accordance with the testing procedures described in ISO 15397:2014, 5.12. Additional information is provided in Annex D.

#### 4.2.2 Coloration of printed parts

##### 4.2.2.1 Validation print system within-sheet uniformity

The variability of the coloration across the validation print format shall be verified by printing each of the three test forms described in 5.4. Each test form shall be measured at nine locations on each sheet as follows. Divide the printed area into thirds both horizontally and vertically and measure at the centre of each area. All selected locations across the printed test area for each test tint, after the stabilization period, shall have the following:

- a) standard deviation less than or equal to 1,5 for CIE L\*, a\* and b\*;

- b) maximum  $\Delta E_{00}$  colour difference less than or equal to 2 units between the average of the 9 readings and any one reading.

NOTE The requirements specified in a) and b) are not statistically consistent but have been observed to be achievable in a well-controlled digital printing system.

The uniformity shall also be measured by using the "Macro-Uniformity-Score" method defined in ISO/TS 18621-21, also known as M-Score. Three tone value combinations specified in 5.4 shall be evaluated as the uniformly tinted area. The "Macro-Uniformity-Score" shall be greater than or equal to 50 and should be greater than or equal to 60.

4.2.2.2 Colour simulation requirements for validation prints

The CIELAB colour coordinates of the patches of the ISO 12642-2 target and the validation print control strip defined in 5.2 shall agree with the aim values of the printing condition being simulated as given by the data (see 4.1) within the appropriate tolerances specified in Table 2.

NOTE 1 The colorimetric aim values for all patches are included in, or can be derived from, the colorimetric values of the reference characterization data set.

**Table 2 — Tolerances for reproduction of all patches in the validation print<sup>a</sup> by comparison to the values of the characterization data of the printing condition being simulated**

Unit: 1

Patch in validation print form	Tolerance
Substrate	$\Delta E_{00} \leq 3,0$
All patches described in 5.2 (without the boundary patches)	95th percentile: $\Delta E_{00} \leq 5,0$ Average: $\Delta E_{00} \leq 2,5$
Patches described in 5.2 c	Average: $\Delta C_h \leq 2,5$ Maximum: $\Delta C_h \leq 4,0 - 8$
Selected surface gamut patches as listed in Annex C (taken from ISO 12642-2)	Average: $\Delta E_{00} \leq 3,0$
All patches described in ISO 12642-2 <sup>b</sup>	Average: $\Delta E_{00} \leq 2,5$ 95th percentile: $\Delta E_{00} \leq 5,0$
Spot colours (solids)	$\Delta E_{00} \leq 3,5$
<sup>a</sup> Described in Clause 5.	
<sup>b</sup> For multicolour reference printing conditions, only the patches in 5.2 shall be used.	

These tolerances apply only to conformance of validation prints as defined in A.1 and A.2. They can also be used for validation prints made for a particular printing condition when tested in the field using only a control wedge. They might be inappropriate as tolerances for daily use at production sites due to the increased production costs required to maintain the equipment in this optimum state.

NOTE 2 It is expected that validation printing system can also reproduce solid spot colours, provided that a clear identification by the CIELAB colour or spectral definition such as ISO 17972-4 (Cx/F/X-4).

NOTE 3 Only when spot colour availability is declared, the declared spot colours are evaluated.

4.2.3 Short- and long-term repeatability

Three validation prints containing at least the primary and CMY secondary colour solids, and primary colour mid-tones shall be produced. There shall be a 1 hour time difference between the production of the first and second print and a one day time difference between the first and third validation print. Recalibration before production of each print is permitted. For each print, measurements shall be made on the first print produced after the vendor-specified stabilization period. The maximum CIEDE2000

CIELAB colour difference between any two of the three samples of each colour shall not exceed the values shown in [Table 3](#).

**Table 3 — Repeatability of primary and CMY secondary colour solids and primary colour mid-tones (CIEDE2000 -colour differences)**

Unit: 1

Type	Solids	Mid-tones (40 % to 50 %)
Validation print	2,0	2,5

NOTE For certain print systems, the same point on a validation print can be formed from a different source on different days; strictly speaking, this is testing reproducibility not repeatability. For these systems, there is no true test of repeatability.

#### 4.2.4 Permanence

##### 4.2.4.1 Print stabilization period

A test should be performed and reported to verify that the print colorant has sufficient resistance to a defined mechanical abrasion after any manufacturer's defined stabilization period. One optional test method is specified in [Annex B](#). In any test, the time required for the validation print solids to reach mechanical stability should not exceed the manufacturer's defined stabilization period. In the case that there is no manufacturer's defined stabilization period, it should not exceed 30 min. This test should be performed for each separate combination of materials, driving software, colorant and printing condition that potentially can change the print stabilization time. If the validation print has been coated, this shall be reported.

##### 4.2.4.2 Fading and light fastness testing

Fading testing shall use the solid tones of the C, M, Y, R, G, B plus K (7 patches). The measurement condition shall be in accordance with ISO 13655:2016, M1 with white backing. Colorimetric calculation shall be in accordance with ISO 13655.

The validation print stabilization period shall be specified by the manufacturer. The variability ("fading") of the C, M, Y, R, G, B plus K patches over time, in the dark, shall not exceed 1,5  $\Delta E_{00}$  colour difference units during the first 24 hours after the print stabilization period.

Four copies of a test form shall be prepared on the validation print substrate, which contain unprinted parts and patches of printed primaries and CMY secondaries both as solids and as midtones. Combinations of all of the process colours used by the validation printing system shall be included in this set, which may include more than four colorants.

Three copies of the test form shall be stored for a print stabilisation period of at least 24 h in the dark under standard atmosphere according to ISO 187 (at 23 °C  $\pm$  1 °C and a relative humidity of 50 %  $\pm$  2 % RH).

The CIELAB colour values of the validation printing substrate and the printed patches shall be measured according to ISO 13655 M0, M1 or M2 on white backing.

Each of the three copies of the test form shall be subjected to one of the following storage conditions.

- 24 h at 25 °C  $\pm$  1 °C and at a relative humidity of 25 %  $\pm$  2 % in the dark.
- 24 h at 40 °C  $\pm$  1 °C and at a relative humidity of 80 %  $\pm$  2 % in the dark.
- One week at 40 °C  $\pm$  1 °C and at a relative humidity of 10 %  $\pm$  2 % in the dark.

For each of these treatments, for the substrate and for all patches of the test form the maximum colour difference between colour values of the patches before and after the treatment shall not exceed 4,5  $\Delta E_{00}$  units.

In cases where validation prints are expected to be used for a longer period of time, light fastness exposure shall be performed using a window glass filtered xenon lamp. It shall meet a light fastness rating of 3 or greater using the blue wool test as described in ISO 12040. This corresponds to a dose of 43 000 kJ/m<sup>2</sup> and a colour difference of  $\Delta E_{00} < 4,5$ .

NOTE 1 Production printing substrates with OVAs are usually less stable than typical inkjet-based validation printing substrates. However, in this case, it is expected that the validation print is stable over time and does not reflect this specific behaviour. It is expected that a typical validation print is not used longer than 3 months, hence a lightfastness test is only informative.

NOTE 2 It is anticipated that window glass application as described in ISO 105-B02<sup>[1]</sup>, such as optical filters, be fitted to minimize short-wavelength light (less than 310 nm).

NOTE 3 For further information or alternative methods on light fastness testing, see ISO 18937<sup>[15]</sup> and ISO 21139-1<sup>[16]</sup>. These International Standards have been recently published and are subject for future use in this document.

### 4.2.5 Ink set gloss

The gloss of solid tone colours should be similar to that of the production print to be simulated. The ink set gloss may be specified if deemed necessary; see 5.6 for one method.

NOTE 1 If the gloss of the final validation print is substantially different from the expected production print, a surface-finishing step (e.g. surface laminate) to raise or lower the gloss can improve the situation.

NOTE 2 The measure of gloss perception is the subject of ongoing appearance research.

### 4.2.6 Tone value reproduction limits

Tints intermediate between the (simulated) substrate white and solid shall transfer onto the validation print in a consistent and uniform manner over a tone value range that includes at least the tone reproduction limits of the printing condition being simulated; see the relevant parts of ISO 12647<sup>[5]</sup>-<sup>[9]</sup> for this information. If the target characterization data set makes no direct reference to ISO 12647, the tone value reproduction limits shall lie between 2 % and 98 %.

NOTE It is good practice to ensure that no significant image part is reliant on tone values outside of the tone value reproduction limits of the expected production printing process.

### 4.2.7 Tonality assessment

The single-colour CMYK patches (ramps), between 30 % and 70 %, described in ISO 12642-2 should be measured. The absolute CIE L\* difference between the measured ramps and those of the reference characterization data should be equal to or less than 2.

NOTE The usage of CIE  $\Delta L^*$  has a better correlation to the perceived tonality than the differences in colorimetric tone values.

### 4.2.8 Reproduction of vignettes

Reproductions of the CMYK data in accordance with image S6 of ISO 12640-1 shall show no visible steps within the tone value reproduction limits (see 4.2.6) if viewed under ISO viewing condition P1 in accordance with ISO 3664.
