

Designation: ~~D7031-04~~ Designation: D7031 – 11

Standard Guide for Evaluating Mechanical and Physical Properties of Wood- Plastic Composite Products¹

This standard is issued under the fixed designation D7031; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide covers test methods appropriate for evaluating a wide range of performance properties for wood-plastic composite (WPC) products. It was developed from evaluations of both experimental and currently manufactured products, and is not intended to suggest that all the tests listed are necessary or appropriate for each application of a WPC. The user must determine which test methods apply to the particular application being evaluated (see Appendix X1).

1.2 Details of manufacturing processes may be proprietary and are beyond the scope of this guide.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 *Definitions*—Terminology used to describe WPCs is defined in Terminology D9, D883, D1038, D1554, D4092, and Classification D4000.

3.2 *Definitions of Terms Specific to this Standard:*

3.2.1 *recycled products*—products composed of post-consumer material or recovered material, or both, that may or may not have been subject to additional processing steps of the types used to make the products.

3.2.2 *thickness*—the lesser dimension perpendicular to the long axis.

3.2.3 *virgin material* —a material that has not been subjected to use or processing other than that required for its initial manufacture

3.2.4 *width*—the greater dimension perpendicular to the long axis.

3.2.5 *wood-plastic composite (WPC)*—a composite made primarily from wood- or cellulose-based materials and plastic(s).

3.3 *Orientation*—WPCs have three principal directions (see Fig. 1).

4. Significance and Use

4.1 WPCs are intended for use in both structural and non-structural applications. The test methods described within are intended to address products that are manufactured from virgin or recycled wood and thermoplastic sources. These methods provide a reference for the evaluation of several mechanical and physical properties important for structural and non-structural uses of WPCs.

³ Available from American Wood-Preservers' Association (AWPA), P.O. Box 388, Selma, AL 36702-0388, <http://www.awpa.com>.

L direction - Parallel to the longitudinal direction of the member (length)
 X direction - Parallel to the wide surface of the member and normal to the L direction (width)
 Y direction - Normal to both the L and X direction (thickness)

FIG. 1 Orientation for Wood-Plastic Composites

5. Determination of Mechanical and Physical Properties

5.1 The following mechanical and physical properties are included to provide a complete set of reference tests for a broad range of users. Some applications of WPCs will not require assessment of all properties. For example, products that will be limited to flexural applications will not require assessment of tension or compression properties.

5.2 *Sampling*—Samples for testing shall be representative of the population being evaluated. Sampling shall be conducted in accordance with applicable portions of Practice D2915 and be representative of the possible variations due to changes in raw materials and process variables over time. It is essential to consider batch-to-batch and shift-to-shift variability when sampling actual production. Test specimens shall be selected from several production runs of a given item.

5.3 *Sample Size*—Selection of a sample size depends upon the property to be estimated, the actual variation in the property occurring in the population, and the precision with which the property is to be estimated. The principles of Practice D2915 shall be followed.

NOTE 1—If code listed allowable design values or performance ratings are the objective, it is recommended that all sampling and testing be conducted or witnessed, or both, by a qualified inspection agency.

5.4 *Conditioning*—Prior to testing, all specimens shall be conditioned to environmental conditions appropriate for the intended end use of the product.

5.4.1 When temperature and relative humidity are important considerations, the test specimens shall be conditioned for a period of time such that the average daily mass change of the test specimen is less than 2 % of the mass at time of measure.

5.4.2 When the product is to be subjected to a water soak environment, the test specimens shall be tested within 30 min upon removal from the treatment.

5.5 *Bending*—Modulus of rupture (*MOR*) or moment capacity and apparent modulus of elasticity (*E*) or flexural stiffness shall be determined in accordance with principles of Test Methods D4761 or D6109. For some applications and products, moment capacity and flexural stiffness are preferable performance measures. Whenever possible, the test specimen shall be the full cross section of the as-manufactured product. Selection of specimen dimensions establishes the unit volume for analysis of volume effects in accordance with Specification D5456, when applicable. A span-to-depth ratio of not less than 16 shall be used. The specimens shall be loaded at a constant strain rate of 1 % per minute (± 10 %). Average time to failure for each test configuration shall be recorded (see X1.5). A constant strain rate of 1 % per minute is achieved by using a constant rate of test machine cross-head motion, *R*, (inches/minute) computed in terms of the test span, *L*, and the member depth, *d*, by the following equation:

$$R = 0.00185 \times \frac{L^2}{d}$$

NOTE 2—WPCs often exhibit exceptionally large deformations prior to failure in bending. Users are cautioned to take particular care in test machine set-up to accommodate large deflections, both in terms of deflection measuring devices and support conditions.

5.5.1 *MOR*—Maximum load for the calculation of *MOR* shall be reported for each specimen. If the calculation is based on a load other than the maximum load, the load basis shall be reported.

NOTE 3—For products that exhibit large deformations, the *MOR* value is commonly based on the load at 3 % strain.

5.5.2 *E*—Apparent flexural modulus of elasticity and its calculation basis shall be reported for each specimen. Characterization of the modulus of elasticity depends upon the use of the data. For material property information, *E* can be calculated in a variety of ways. For design value assignment purposes linear least squares fit of the stress-strain curve over an appropriate range of stress shall be used.

NOTE 4—To assign design values to structural members the least squares fit over a range of 10 to 40 % of ultimate stress is commonly chosen as representative for service loadings. An alternative calculation method based on the secant modulus to 1 % strain is commonly used for all-plastic products.

5.6 *Tension Parallel to the L Direction*—Tension strength parallel to the *L* direction shall be evaluated by testing in accordance with the principles of Test Methods D4761. Specimen cross section shall not be less than the minimum anticipated structural size. Specimen length between grips shall be a minimum of 12 times the actual test specimen width. The specimens shall be loaded at a constant strain rate of 1 % per minute (± 10 %). Average time to failure for each test configuration shall be recorded. If required, selection of specimen dimensions establishes the unit volume for the analysis of volume effects per Specification D5456.

5.7 *Compression Parallel to the L directionDirection*—Short column compression strength parallel to the *L* direction shall be determined in accordance with the principles of Test Methods D4761. Tests shall be conducted on a cross section no less than the minimum anticipated structural size. Length of the specimen shall be such that *l/d* is less than 4.5 and greater than 3.0, where *l* is the effective unsupported length and *d* is the minimum cross-sectional dimension. For non-solid cross-section materials, the actual cross-sectional area shall be calculated.

5.8 *Compression Perpendicular to the L directionDirection*—Compression strength perpendicular to the *L* direction shall be determined following the measurement and bearing requirements of Test Method D143, except that the specimen dimensions shall be the full cross-section dimension of the WPC, and the length shall be three times the depth. Load shall be applied through a metal bearing plate across the full width of the test specimen. Stress at both 0.02 and 0.04 in. (0.5 and 1.0 mm) of deformation shall be reported. Testing shall be conducted with stresses applied normal to the *L-X* or *L-Y* plane, or both, when required for general

product application. The objective of this test is to determine the load carrying capacity of the as-manufactured product. The allowable stress derived from this test will only apply to the actual cross section tested.

5.9 Shear Strength:

5.9.1 ~~Shear Parallel to the L direction (longitudinal shear)~~ Shear Parallel to the L Direction (Longitudinal Shear)—Shear strength parallel to the *L* direction shall be determined in accordance with the principles of Test Method D143 using the shear block test. Testing shall be done to produce shear failure in the *L-X* or *L-Y* plane, or both. For solid cross-section products, a minimum dimension of 1.0 in. (25 mm) in the shear area is acceptable provided that the total shear area is at least 1.0 in². For non-solid cross-section products, the full cross section shall be tested using the shear block tests with the actual shear area based on wall thickness(s) subjected to the shearing stress.

5.9.2 ~~Shear Perpendicular to the L direction~~ Direction—Shear strength perpendicular to the *L* direction shall be determined in accordance with the principles of Test Method D143 using the shear block test. The Test Method D143 shear block test has been shown to provide a conservative estimate of the shear strength of wood-based materials. Other test methods may be applicable. Testing shall be done to produce shear failure in the *X-Y* plane. For solid cross-section products a minimum dimension of 1.0 in. (25 mm) in the shear area is acceptable provided that the total shear area is at least 1.0 in².

NOTE 5—For non-solid cross-section products, a shear block test perpendicular to the *L* direction may not be practical. For some special cases, such as nonhomogeneous materials or non-solid cross-section products, alternative test methods such as Test Method D5379/D5379M, will provide additional insight into actual shear strength material properties.

5.10 Creep-Recovery and Creep-Rupture:

NOTE 6—When building code listed design values are the objective of the investigation, consideration of creep-recovery and creep-rupture are generally required.

5.10.1 *Creep-Recovery*—A minimum of ten specimens representative of the population being sampled shall be loaded in flexure in accordance with 5.5 to a bending stress appropriate for the intended end use. The test specimens are loaded for 24 h, unloaded, and allowed to recover with no load for 24 h. Deflection at mid-span is measured a minimum of four times: (1) prior to the application of load, (2) at 24 h with load on, (3) within one minute after the load is removed, and (4) after the 24-h recovery period. Total deflection is the amount of deflection that occurred during the first 24-h period. The percent recovery for each test specimen is defined as the recovered deflection times 100, divided by the total deflection. The average percent recovery, rounded to the nearest percent shall be reported.

5.10.2 *Creep-Rupture*—A minimum of ten specimens representative of the population being sampled shall be loaded in flexure in accordance with 5.5 to a stress level appropriate for the intended end use. Prior to loading, the test specimens shall be allowed to equilibrate to the test temperature conditions (for example, 68 ± 4°F (20 ± 2°C)) and be maintained throughout the experiment. The load shall be maintained for a minimum of 90 days with deflection measurements taken at regular intervals to adequately describe the creep curve. It is recommended that for the first eight hours, measurements be taken hourly, for the following 24 h, measurements at eight-hour intervals are suggested, followed by daily measurements for the next ~~7~~ seven days. Weekly measurements should be adequate for the remainder of the 90-day period unless there is evidence of tertiary creep (increasing creep rate).

NOTE 7—It is recognized that maintaining a constant temperature for a long period of time may be difficult. It is, therefore, recommended that temperature be recorded with a frequency sufficient to establish the magnitude and duration of temperature fluctuations.

5.11 *Mechanical Fastener Holding Tests*—When testing WPC materials for fastener holding properties, the principles of Test Methods D1037, D1761, or D5764 shall be followed with the following exception: conditioning of the test material prior to specimen preparation shall be conducted in accordance with 5.4. Testing with nails, screws, and staples, when required, shall be performed in accordance with Test Methods D1037 or D1761. Testing with bolts, when required, shall be in accordance with Test Method D5764.

NOTE 8—The procedures of Annex A2 on Establishing Equivalent Sawn Lumber Species Connection Properties for SCL of Specification D5456 have been accepted by model code evaluation services for WPCs as an alternative method of establishing connection properties.

5.12 *Impact Resistance*—Depending upon the objective of the testing program, Test Methods D4495 or E661 shall be used to determine the impact resistance of WPCs. When required for a specific product application, this test shall be conducted on each surface where impacts are possible in service. The diameter of the impact weight in Test Method D4495 shall be 1.0 in. (25 mm) producing a contact area of 0.785 in².

NOTE 9—For non-solid cross-section materials, the impact strength may be measured at several locations on the surface to determine the effect of the cross-section geometry.

5.13 Fire Performance:

5.13.1 Flame spread shall be determined using Test Method E84.

5.13.2 Other fire performance properties may be determined using Test Methods E1354 or D1929, as appropriate. These test methods provide an assessment of one or more of the following properties: smoke release rate, mass loss rate, heat release rate, and ignition temperatures.

5.14 *Specific Gravity*—Specific gravity specimens may be taken from an undamaged portion of each bending test specimen and
