### Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see <a href="https://www.iso.org/directives">www.iso.org/directives</a>).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see <a href="https://www.iso.org/patents">www.iso.org/patents</a>).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see www.iso.org/iso/foreword.html.

This document was prepared by Technical Committee ISO/TC 201, *Surface chemical analysis*, Subcommittee SC 9, *Scanning probe microscopy*.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at <u>www.iso.org/members.html</u>.

### Introduction

Atomic force microscope (AFM) is a method for imaging surfaces by mechanically scanning their surface contours, in which the deflection of a sharp probe tip sensing the surface forces, mounted on a compliant cantilever, is monitored. AFM belongs to a family of scanning probe microscope (SPM) and is of increasing importance for the characterization of materials surfaces at the nanoscale. Therefore, precise and quantitative measurement of three-dimensional (3D) surface topography at the nanoscale by AFM is highly demanded by researchers and engineers in the various fields of academia and industry. One of the imaging artefacts of AFM topography measurements is caused by the finite size and shape at the apex of an AFM probe used for the scanning. Such a dilation effect due to the probe shape can cause a significant error in the precise analysis of 3D surface morphology. Especially for the critical dimension (CD) analysis of fine devices at the nanoscale, there is a need for probe-shape artefact to be corrected in a reproducible and quantitative way. Thus, the demand for the establishment of an international standard on the guideline for a reliable restoration procedure of dilated AFM images is high.

This document describes a quantitative procedure for the restoration of AFM height images dilated by finite probe size and shape. It includes the quantitative characterization of AFM probe apex in use and the restoration of AFM topography images using the actual probe shape.

### Surface chemical analysis — Atomic force microscopy — Guideline for restoration procedure for atomic force microscopy images dilated by finite probe size

#### 1 Scope

This document describes a procedure for the quantitative characterization of the probe tip of an atomic force microscope (AFM) probe and a restoration of AFM topography images dilated by finite probe size. The three-dimensional shape of the probe apex is extracted by image reconstruction using suitable reference materials. This document is applicable to the reconstruction of AFM topography images of solid material surfaces.

#### 2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO 11775, Surface chemical analysis — Scanning-probe microscopy — Determination of cantilever normal spring constants

- IEC Electropedia: available at <u>https://www.electropedia.org/</u>

### 3.1

#### dilation

one of the two basic operators of mathematical morphology, whose basic effect on a binary image is to gradually enlarge the boundaries of regions of foreground pixels

Note 1 to entry: The dilation  $(\bigoplus)$  of a set *A* by a set *B* is defined as follows:

$$A \oplus B = \bigcup_{b \in B} (A + b)$$

Note 2 to entry: By dilation, areas of foreground pixels grow in size while holes within those regions become smaller.

#### 3.2

#### erosion

one of the basic operators of mathematical morphology, whose basic effect on a binary image is to erode away the boundaries of regions of foreground pixels

Note 1 to entry: The erosion  $(\bigcirc)$  of a set *A* by a set *B* is defined as follows:

$$A-B = \bigcup_{b \in B} (A-b)$$

Note 2 to entry: By erosion, areas of foreground pixels shrink in size, and holes within those areas become larger.

#### 3.3

#### mathematical morphology

theory and technique for the analysis and processing of geometrical structures, based on set theory, lattice theory, topology, and random functions, which is commonly applied to digital images

Note 1 to entry: See Reference [4]

#### 3.4

#### probe

structure at or near the end or apex if the cantilever designed to carry the probe tip (3.8)

[SOURCE: ISO 18115-2:2021, 5.109]

#### 3.5

## probe characterizer iTeh STANDARD PREVIEW

#### tip characterizer

structure designed to allow extraction of the probe tip (3.8) shape from a scan of the characterizer

#### 3.6

#### probe shape characteristic **PSC**

relationship between the probe profile width and the probe profile length for a given probe projected onto a defined plane

[SOURCE: ISO 13095:2014, 3.10]

#### 3.7

#### probe shape function

**PSF** 

matrix representing a three-dimensional shape of a probe tip (3.8) used for AFM imaging

3.8 probe tip tip probe apex structure at the extremity of a probe (3.4), the apex of which senses the surface

[SOURCE: ISO 18115-2:2021, 5.120]

#### 3.9

#### reconstruction

estimate of the sample's (or tip's) surface topography determined by removing from the image the effect of the tip's (or sample's) shape and other measurement artefacts

[SOURCE: ISO 18115-2:2021, 5.132]

#### 4 Symbols (and abbreviated terms)

The symbols and abbreviated terms are:

AFM Atomic force microscopy

- I A function describing the measured topography image of a sample by AFM; z(x,y)
- *S* A function representing the true topography image of a sample; s(x,y)
- T A function representing the shape by a probe apex of AFM; t(x,y)
- $S_r$  A function representing the reconstructed topography image of a sample by AFM;  $s_r(x,y)$
- *P* A function describing the reflection of the probe shape *T* through the origin; p(x,y) = -t(-x,-y)
- $P_r$  A function representing the reconstructed image of the reflected-tip shape;  $p_r(x,y)$
- R Tip radius
- A symbol representing a dilation operation in mathematical morphology
- A symbol representing an erosion operation in mathematical morphology

#### 5 Mathematical morphology modelling

For quantitative morphology imaging of nano-objects, it should be noted that significant distortion in imaging may occur if the surface of a nano-object has large corrugation compared to the size and shape of the probe tip<sup>[5]</sup>. When the sample surface is relatively flat on the atomistic scale, it is suitable to express the influence of the probe shape on the AFM topography imaging by the convolution integral with the probe shape. On the other hand, when the unevenness or roughness of the sample surface is somewhat larger than the atomic size, it is more appropriate to express the AFM imaging by dilation which is one of the fundamental operators of mathematical morphology, where the location on the top apex of a probe tip approaching closest to or making a point contact with the sample surface is most important. Interaction from any other area which does not make any contact or near-contact with the sample surface is not considered. The operation of dilation is expressed by Formula (1):

$$z(x, y) = \max\{s(x', y') - t(x' - x, y' - y)\} = \max\{s(x', y') + p(x - x', y - y')\}$$
(1)

Here, I = z(x, y) is a function describing the measured image of the top surface of the sample, while S = s(x, y) is a function representing the true surface morphology. Meanwhile probe shape function T = t(x, y) represents the probe shape describing the surface of the probe tip, where the coordinates of the topmost point of the tip are set as the origin. Finally, P = p(x, y) means -t(-x, -y), describing the reflection of the probe shape T through the origin, which may refer to *reflected tip*. The relationship between the sample S, tip T, image I, and the reflected tip P can be written using the dilation operation  $\bigoplus$  as shown in Formula (2):

$$I = S \oplus (-T) = S \oplus P \tag{2}$$

On the contrary, the reconstruction of the actual surface morphology from the measured AFM image and the probe shape function is expressed as an erosion operation ( $\ominus$ ) in the concept of mathematical morphology. The reconstructed surface morphology  $S_r = s_r(x, y)$  is described by Formulae (3) and (4):

$$s_{r}(x,y) = \min\{z(x',y') - p(x'-x,y'-y)\} = \min\{z(x',y') + t(x-x',y-y')\}$$
(3)

$$S_r = I \ominus P$$

It should be noted that  $S_r$  is the least upper bound on the actual surface, and not necessarily equal to S. Since  $I = S \oplus P$ ,

$$S_r \supseteq S$$
 (5)

By the processing of the dilation and erosion operations, while scanning the AFM probe of the finite size, the measured and reconstructed AFM images can be expressed as shown in Figure 1. As described by Formula (5), there exist non-reconstructable regions or hole regions where the tip of the probe cannot reach due to its finite size. Therefore,  $S_r$  is the best reconstruction because it is the surface of the deepest penetration with the probe tip.

# Figure 1 — Mathematical morphology modelling for AFM topography imaging (dilation processing) and image reconstruction (erosion processing)

#### 6 Procedure of restoration of AFM topography images

#### 6.1 General

This clause describes the general procedure for the recovery of dilated AFM topography images. Firstly, the AFM topography images of the reference nanostructures with given shapes, dispersed on flat substrates, are acquired. Then, the probe shape function of the apex of an AFM probe in use is determined by the numerical calculation. Then, by erosion operation using the probe shape function, the most probable surface morphology shall be extracted from the observed AFM topography image of an unknown actual sample (see examples in <u>Annex A</u>).

#### 6.2 Calibration of measuring systems

Calibration of the measuring systems used for AFM topography imaging shall be carried out using certified standards with proper intervals. For example, the calibration of X-, Y- and Z-axes piezoelectric

(4)

scanners are primary prerequisite for the precise topography imaging by AFM. The calibration of the lateral scan axes, or X- and Y-axes of the measuring system, shall be done with one-dimensional (1D) or two-dimensional (2D) lateral standards. Calibration of Z-axis of AFM shall be done by using a set of step height standards in accordance with ISO 11952.

The deflection sensitivity and normal spring constant of a cantilever probe used for the measuring system shall be calibrated properly in accordance with ISO 11775.

#### 6.3 Environment requirements

It is recommended that the measurement be performed in controlled and stable conditions with the temperature stable within  $\pm 1$  °C or better to minimize the drift of the measuring system. It is also recommended to carefully measure the drift rate of the measuring system in accordance with ISO 11039.

#### 6.4 Extraction of probe tip shape using certified reference materials

It is possible to reconstruct the probe tip shape of a force sensor from AFM topography images of certified reference materials called a probe characterizer (or a tip characterizer), whose actual surface morphology, *I* is well characterized. Using erosion operation, reconstructed reflected-tip shape  $P_r$  shall be extracted using Formula (6):

$$P_{\rm r} = I \ominus S \tag{6}$$

Analogously to the reconstruction of a specimen surface,  $P_r$  is the best reconstruction and an outer bound on the probe tip shape. From the known surface morphology of a probe characterizer, the unevenness area whose abruptness is like or larger than that of the probe tip shall be taken as the operation area.

An example of certified reference materials with known shape is standard nanosphere particles dispersed on flat substrates<sup>[6]</sup>. The particle size standards are provided with certain certificates of calibration and traceability by photon correlation spectroscopy (PCS), transmission electron microscopy (TEM), or other techniques.

#### 6.5 Estimation of probe tip shape by blind reconstruction

Blind reconstruction is a type of reconstruction based on the theory and technique of mathematical morphology. The use of blind reconstruction methodology allows characterizing the 3D shape of a probe tip used for AFM topography imaging<sup>[Z]</sup>. Blind reconstruction takes advantage of the self-imaging effect that is present in AFM topography imaging on relatively flat surfaces with exceptionally fine protrusions at the nanoscale. All the nanoscale protrusions observed in AFM topography imaging may be regarded as reflected-tip images, each broadened in different ways by the different underlying surface features. The reflected-tip shape P and the image I satisfy Formula (7):

$$(I \ominus P) \oplus P = I \tag{7}$$

The blind reconstruction method is an iterative solution of the above Formula (7) for a set  $P_{r'}$  which is an outer bound on the true shape of the reflected-tip. The solution shall be obtained iteratively by Formula (8):

$$P_{i+1} = \bigcap_{x \in I} \left( \left( (I-x) \oplus P_i'(x) \right) \cap P_i \right)$$
(8)
