Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of technical committees is to prepare International Standards. Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

ISO 21360-1 was prepared by Technical Committee ISO/TC 112, Vacuum technology.

This second edition cancels and replaces the first edition ISO 21360-1:2012, of which it constitutes a minor revision. The changes compared to the previous edition are as follows:

- Note in 3.3 has been deleted
- K_0 in 3.7 has been corrected
- Jelstanda 3.9 the definition of the volume has been changed to "is the volume of transported gas"
- Figure 1 has been corrected
- Figure 2 has been corrected
- 5.2.7: change to "for at least 60s" instead of "for the following minute".

A list of all parts in the ISO 21360 series can be found on the ISO website.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at <u>www.iso.org/members.html</u>.

Introduction

This part of ISO 21360 is a basic standard for measuring the performance data of vacuum pumps. The methods specified here are well known from existing national and International Standards. In developing this part of ISO 21360, the aim has been to provide a single document containing the measurements of performance data of vacuum pumps and to simplify the future development of specific vacuum pump standards.

Specific vacuum pump standards will contain a suitable selection of measurement methods from this part of ISO 21360 in order to determine the performance data, limiting values and specific operational conditions on the basis of the specific properties of the particular kind of pump. Whenever a discrepancy exists between this part of ISO 21360 and the specific standard, it is the specific standard which is valid.

Vacuum technology — Standard methods for measuring vacuum-pump performance —

Part 1: General description

1 Scope

This part of ISO 21360 specifies three methods for measuring the volume flow rate and one method each for measuring the base pressure, the compression ratio, and the critical backing pressure of a vacuum pump.

The first method for measuring the volume flow rate (the throughput method) is the basic concept, in which a steady gas flow is injected into the pump while the inlet pressure is measured. In practice, the measurement of gas throughput may be complicated or inexact. For this reason, two other methods are specified which avoid the direct measurement of throughput.

The second method for measuring the volume flow rate (the orifice method) is used when there is very small throughput at very small inlet pressures (under a high or ultra-high vacuum). It is based on measuring the ratio of pressures in a two-chamber test dome in which the two chambers are separated by a wall with a circular orifice.

The third method for measuring the volume flow rate (the pump-down method) is well suited for automated measurement. It is based on the evacuation of a large vessel. The volume flow rate is calculated from two pressures, before and after a pumping interval, and from the volume of the test dome. Different effects, such as leak and desorption rates, gas cooling by nearly isentropic expansion during the pumping interval, and increasing flow resistance in the connection line between test dome and pump caused by molecular flow at low pressures, influence the results of the pressure measurement and the resulting volume flow rate.

The choice of the required measurement methods depends on the properties of the specific kinds of vacuum pump, e.g. the measurement of the critical backing pressure is only necessary for vacuum pumps which need a backing pump. All data that are measured on a vacuum pump, but not specified in this part of ISO 21360 (e.g. measurement of power consumption), are defined in the specific pump standard.

2 Normative references

The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO 3529-2, Vacuum technology — Vocabulary — Part 2: Vacuum pumps and related terms

3 Terms and definitions

For the purposes of this document, the terms and definitions given in ISO 3529-2 and the following apply.

3.1 volume flow rate

- q_V
- $q_V = \frac{\mathrm{d}V}{\mathrm{d}t}$ where
- is volume; V
- is time t

[SOURCE: ISO 80000-4:2006^[4], 4-30]

EXAMPLE In the context of this part of ISO 21360, the volume flow rate is the volume of gas which, under ideal conditions, flows from the test dome through the pump inlet per time.

Note 1 to entry: For practical reasons, the volume flow rate of a given pump and for a given gas is conventionally considered to be equal to the quotient of the throughput of this gas and of the equilibrium pressure at a given location. The volume flow rate is expressed in cubic metres per hour or litres per second.

Note 2 to entry: The term "pumping speed" and symbol "S" are often used instead of "volume flow rate".

3.2

inlet pressure

 p_{1}, p_{d}, p_{e}

pressure at the inlet of the pump, measured at a defined location in the test dome

3.3

base pressure

pressure obtained in the test dome after conditioning the vacuum pump and the test dome Note 1 to entry: See <u>5.4</u>. **3.4 maximum working pressure**

 $p_{1 \text{max}}$

highest pressure on the inlet side that the vacuum pump and the driving device can withstand for a $\frac{1}{2}$ prolonged period of operation time without being damaged

3.5

backing pressure

 p_3

pressure at the outlet of a vacuum pump

3.6

critical backing pressure

 $p_{\rm c}$

maximum backing pressure for which the conditions are defined in the instruction manual or in a specific standard for the particular vacuum pump

3.7

compression ratio

K_0

compression ratio without gas load, wherein p_{b3} is the base pressure of the backing pump and p_{b1} is the base pressure of the test pump

$$K_0 = \frac{p_3 - p_{b3}}{p_1 - p_{b1}}$$

3.8

test dome

special vacuum vessel with precisely defined size, diameter and connection flanges on specified locations, used for standard performance data measurements on vacuum pumps

3.9 throughput Q

amount of gas flowing through a duct, expressed by the formula:

$$Q = \frac{p_1 V}{t} = p_1 q_V$$

where

- p_1 is the (high) vacuum pressure on the inlet;
- q_V is the volume flow rate of the test pump;

is time; t

is the volume of transported gas V

3.10

standard gas flow rate

 $q_{V \mathrm{std}}$ - 321 18703/351/189920 5021300-1-2020 volume flow rate at standard reference conditions, i.e. 0 °C and 101 325 Pa

5 Test methods

5.1 Volume flow rate (pumping speed) measurement by the throughput method

5.1.1 General

The throughput method is the one most used for vacuum pumps and is applicable to all pressure ranges and pump sizes where flow meters for gas throughput measurements are available with sufficient accuracy. The gas flow measuring ranges shall be chosen by multiplying the expected volume flow rate by the maximum and minimum working pressure of the test pump.

All measuring devices shall be calibrated either:

a) in a traceable way to a vacuum primary or to a national standard, or

b) by means of instruments of absolute measure which are traceable to the SI units and to which measurement uncertainties can be attributed.

In the case of calibrated measuring instruments, there should exist a calibration certificate in accordance with ISO/IEC $17025^{[3]}$.

5.1.2 Test dome for the throughput method

For these measurements, use a test dome as shown in Figure 1 with the same nominal diameter, D_N , as that of the pump inlet. The face of the dome opposite the inlet flange may be flat, conical or slightly curved, with the same average height above the flange as the flat face. Three flanges are preferable for pressure measurement at a height of D/2 above the bottom flange if more than one pressure gauge is used. The diameter of these flanges should be greater than or equal to the flanges of the gauges used, and their mounting dimensions shall be noted. No measuring port shall be located in the angle range $\pm 45^{\circ}$ next to a gas inlet port. The connection pipes between flange and dome shall not protrude beyond the dome wall on the inside, with the exception of the gas inlet pipe.

If necessary for the test pump, the test dome shall be fitted with a device for bake-out that ensures uniform heating of the dome to achieve the base pressure.

The volume of the test dome may depend on the pump type. Refer to the specific pump standard for details.

For pumps with an inlet flange diameter of less than $D_N = 100$ mm, the diameter of the dome shall correspond to $D_N = 100$ mm. The transition to the pump inlet flange shall be made through a 45° conical adaptor, as shown in Figure 1.

Key

- 1 gas inlet pipe and temperature measuring point for $T_{\rm D}$
- 2 vacuum gauge and mass spectrometer connections
- *D*_i diameter of the inlet pipe
- *D* inner diameter of test dome, in metres

NOTE D_i should be big enough to allow homogenous gas conditions at the pump flange. A diameter of 0,1*D* is generally appropriate.

Figure 1 — Test dome for the throughput method
