

Designation: D6521 – 13

## Standard Practice for Accelerated Aging of Asphalt Binder Using a Pressurized Aging Vessel (PAV)<sup>1</sup>

This standard is issued under the fixed designation D6521; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon ( $\epsilon$ ) indicates an editorial change since the last revision or reapproval.

### 1. Scope

1.1 This practice covers the accelerated aging (oxidation) of asphalt binders by means of pressurized air and elevated temperature. This is intended to simulate the changes in rheology which occur in asphalt binders during in-service oxidative aging but may not accurately simulate the relative rates of aging. It is normally intended for use with residue from Test Method **D2872** (RTFOT), which is designed to simulate plant aging.

NOTE 1—Modified asphalt binders may phase separate or form skins during oven conditioning in Test Method **D2872** (RTFOT); the results from subsequent testing of this residue may not be representative of modified asphalts short-term aged under field conditions. Phase separation, or formation of skins, or both can also occur during PAV conditioning. Therefore, the practice may not be suitable for some modified asphalts.

NOTE 2—PAV conditioning has not been validated for materials containing particulate materials.

1.2 The aging of asphalt binders during service is affected by ambient temperature and by mixture-associated variables, such as the volumetric proportions of the mix, the permeability of the mix, properties of the aggregates, and possibly other factors. This conditioning process is intended to provide an evaluation of the relative resistance of different asphalt binders to oxidative aging at selected elevated aging temperatures and pressures, but cannot account for mixture variables or provide the relative resistance to aging at in-service conditions.

1.3 The values stated in SI units are to be regarded as the standard. Values in parentheses in inch-pound units are provided for informational purposes only.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

<sup>1</sup> This practice is under the jurisdiction of ASTM Committee **D04** on Road and Paving Materials and is the direct responsibility of Subcommittee **D04.46** on Durability and Distillation Tests.

Current edition approved Sept. 1, 2013. Published September 2013. Originally approved in 2000. Last previous edition approved in 2008 as D6521 – 08. DOI: 10.1520/D6521-13.

### 4. Summary of Practice

4.1 Asphalt binder is normally first conditioned using Test Method **D2872** (RTFOT). Residue from the RTFOT is then placed in standard stainless steel pans and aged at the specified conditioning temperature for 20 h in a vessel pressurized with air to 2.10 MPa. The conditioning temperature is selected according to the grade of asphalt binder. The residue is then vacuum degassed.

5. Significance and Use

5.1 This practice is designed to simulate the in-service oxidative aging that occurs in asphalt binders during pavement service. Residue from this conditioning practice may be used to estimate the physical or chemical properties of asphalt binders after several years of in-service aging in the field.

5.2 Binders conditioned using this practice are normally used to determine specification properties in accordance with Specification D6373 or AASHTO M 320.

5.3 For asphalt binders of different grades or from different sources, there is no unique correlation between the time and temperature in this conditioning practice and in-service pavement age and temperature. Therefore, for a given set of in-service climatic conditions, it is not possible to select a single PAV conditioning time, temperature and pressure that will predict the properties or the relative rankings of the properties of asphalt binders after a specific set of in-service exposure conditions.

5.4 The relative degree of hardening of different asphalt binders varies with conditioning temperatures and pressures in the PAV. Therefore, two asphalt binders may age at a similar rate at one condition of temperature and pressure, but age differently at another condition. Hence, the relative rates of aging for a set of asphalts at PAV conditions may differ

significantly from the actual in-service relative rates at lower pavement temperatures and ambient pressures.

6. Apparatus

6.1 An equipment system consisting of a pressure vessel, ovens, pressure-controlling devices, temperature-controlling devices, pressure and temperature measuring devices, and a temperature and pressure recording system (see Fig. 1).

6.1.1 *Pressure Vessel*—A stainless steel pressure vessel designed to operate at  $2.1 \pm 0.1$  MPa between 90 and 110°C with interior dimensions adequate to hold ten PAV pans and a pan holder. The pan holder shall be capable of holding ten PAV stainless steel pans in a horizontal (level) position, such that the asphalt binder film thickness is reasonably uniform. The holder shall be designed for easy insertion and removal from the vessel when the holder, pans, and asphalt binder are at the conditioning temperature. A schematic showing a possible configuration of the vessel, pan holder and pans, and specifying dimensional requirements is shown in Fig. 2.

NOTE 3—The vessel may be a separate unit to be placed in a forced draft oven for conditioning the asphalt binders or an integral part of the temperature control system (for example, by direct heating of the vessel or by surrounding the vessel with a permanently affixed heating unit, forced air oven, or liquid bath). For practical purposes, it is recommended that the vessel have the dimensions of 250 mm in diameter and 265 mm in height.

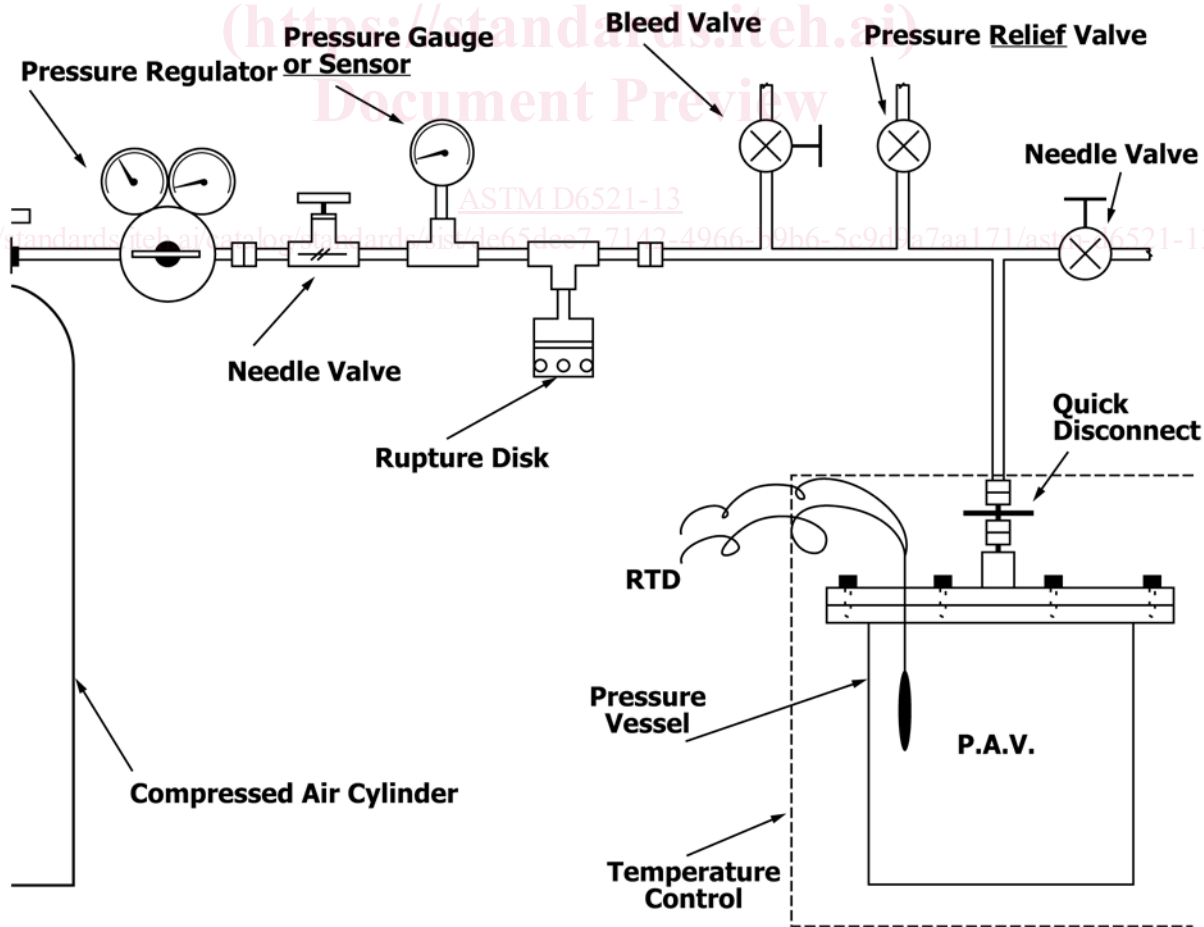

FIG. 1 Schematic of PAV Test System

FIG. 2 Schematic Showing Location of Pans and RTD Within PAV

NOTE 1—Distance “a” controls the levelness of the pan. The assembly shall be supported at three or more support points. The distance “a,” measured from each assembly support point to the bottom of the pan (top of shelf or pan support point), shall be controlled to  $\pm 0.05$  mm.

NOTE 2—Distances  $b_1$  and  $b_2$  shall be such that any active portion of the temperature transducer is  $\geq 10$  mm from any adjacent surface.

NOTE 3—Distance “c” shall be  $\geq 12$  mm.

#### 6.1.2 Pressure and Temperature Controlling Devices:

6.1.2.1 A pressure relief valve that prevents pressure in the vessel from exceeding the design pressure of the vessel, but in no case exceeding 2.5 MPa during the conditioning procedure.

6.1.2.2 A pressure regulator or regulating system capable of controlling the pressure within the vessel to  $\pm 0.02$  MPa, and with a capacity adequate to reduce the pressure from the source of compressed air, so that the pressure within the loaded pressure vessel is maintained at  $2.1 \pm 0.1$  MPa gauge (relative) pressure during the conditioning process.

6.1.2.3 A slow-release bleed valve or pressure controller that allows the pressure in the vessel at the completion of the conditioning procedure to be reduced from 2.1 MPa to local atmospheric pressure within 8 to 15 min.

6.1.3 Temperature Controlling Device—A digital temperature control device as described in 6.1.4.1 or 6.1.4.2 for maintaining the temperature during the conditioning procedure within the pressure vessel at the conditioning temperature  $\pm 0.5^\circ\text{C}$ .

6.1.3.1 A heating device (forced-draft oven or fluid bath) capable of restoring the conditioning temperature within the vessel after loading the pans and the pan holder and prior to pressurizing the vessel within 2 h of placing the loaded vessel in the heating device. The device shall be capable of maintaining the temperature within the pressure vessel at the conditioning temperature  $\pm 0.5^\circ\text{C}$ . If an oven is used, the oven shall have sufficiently large interior dimensions to allow forced air to freely circulate within the oven and around the pressure vessel when the vessel is placed in the oven. The oven shall contain

a stand or shelf that supports the loaded pressure vessel in a level position above the lower surface of the oven.

6.1.3.2 A pressure vessel with an integral temperature control system that is capable of restoring the pre-conditioning temperature, as determined in 9.3, within the vessel after loading the pans and the pan holder, prior to pressurizing the vessel within 2 hours of placing the loaded vessel in the heating device, and maintaining the temperature within the pressure vessel at the conditioning temperature  $\pm 0.5^\circ\text{C}$ .

NOTE 4—Preheating the pressure vessel may be necessary to achieve the conditioning temperature within the required 2-h period.

#### 6.1.4 Temperature and Pressure Measuring Devices:

6.1.4.1 A platinum resistive thermometric device (RTD) accurate to the nearest  $0.1^\circ\text{C}$  and manufactured in accordance with Specification E1137/E1137M (IEC 751), or equal, for measuring temperature inside the pressure vessel. The RTD shall be calibrated as an integral unit with its respective metre or electronic circuitry.

6.1.4.2 Temperature Recording Device—A strip chart recorder or other data acquisition system capable of recording temperature throughout the conditioning process to within  $\pm 0.1^\circ\text{C}$  at a minimum interval of once per minute. As an alternative, an electronic device capable of reporting only maximum and minimum temperatures (accurate to  $\pm 0.1^\circ\text{C}$ ) may be used.

6.1.4.3 A pressure gauge capable of measuring the pressure in the pressure vessel to within  $\pm 0.02$  MPa during the conditioning process.
