Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of ISO document should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

ISO draws attention to the possibility that the implementation of this document may involve the use of (a) patent(s). ISO takes no position concerning the evidence, validity or applicability of any claimed patent rights in respect thereof. As of the date of publication of this document, ISO had not received notice of (a) patent(s) which may be required to implement this document. However, implementers are cautioned that this may not represent the latest information, which may be obtained from the patent database available at www.iso.org/patents. ISO shall not be held responsible for identifying any or all such patent rights.

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see www.iso.org/iso/foreword.html.

This document was prepared by Technical Committee ISO/TC 154, *Processes, data elements and documents in commerce, industry and administration*.

A list of all parts in the ISO 8601 series can be found on the ISO website.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at www.iso.org/members.html.

Date and time — Representations for information interchange —

Part 2: Extensions

AMENDMENT 1: Canonical expressions, extensions to time scale components and date time arithmetic

3.1.2

Add the following terminological entries after 3.1.2.13:

3.1.2.14

canonical form

date and time expression where all its time scale components are *normalised* ([3.1.2.15](#))

Note 1 to entry: The canonical form of a date and time expression implies it contains minimal underflow and no overflow.

3.1.2.15

normalise

process to ensure time scale components have values in their defined inclusive ranges

3.1.2.16

normalised duration

duration whose time scale components have values that are *normalised* ([3.1.2.15](#))

Note 1 to entry: This also applies to negative durations.

3.1.2.17

overflow

state of a time scale component with a positive value when paired with a higher-order time scale component it is unequivocally convertible with, that holds a value representing a duration exceeding one unit of the higher-order time scale component

Note 1 to entry: A time scale component can only be in overflow when considered against a higher-order time scale component it is unequivocally convertible with.

Note 2 to entry: The state of overflow is considered resolved if the time scale component has a value representing a duration less than one unit of the higher-order time scale component.

EXAMPLE 1 A calendar day time scale component representing 10 calendar days is considered in overflow when the higher-order time scale component considered is a calendar week, as the calendar day and calendar week are an unequivocally convertible time scale component pair.

EXAMPLE 2 A calendar day time scale component representing 35 calendar days is not considered in overflow when the higher-order time scale component considered is a calendar month, as the calendar day and calendar month are not an unequivocally convertible time scale component pair.

**3.1.2.18
underflow**

state of a time scale component with a negative value when paired with a higher-order time scale component it is unequivocally convertible with, where the result of combining the duration represented by the higher-order time scale component and the duration represented by the lower-order time scale component is larger than or equal to zero

Note 1 to entry: A time scale component can only be in underflow when considered against a higher-order time scale component it is unequivocally convertible with.

Note 2 to entry: In resolving time scale component underflows, the negative value of the lower-order time scale component can be expressed in a semantically equivalent form using a combination of the lower-order and higher-order time scale components with values for both larger than or equal to zero.

EXAMPLE 1 A calendar month time scale component representing -8 calendar months is considered in underflow when the higher-order time scale component considered is a calendar year with a value of 1 (which is equivalent to 12 calendar months), as the calendar month and calendar year are an unequivocally convertible time scale component pair.

EXAMPLE 2 A calendar day time scale component representing -60 calendar days is not considered in underflow when the higher-order time scale component considered is a calendar month, as the calendar day and calendar month are not an unequivocally convertible time scale component pair.

EXAMPLE 3 A calendar day time scale component representing -10 calendar days is considered in underflow when the higher-order time scale component considered is a calendar week with a value of 2, but it is not considered in underflow when the calendar week has a value of 1, since a calendar week is equivalent to 7 calendar days, which when combined with -10 calendar days results in a duration less than zero.

14.5

Add the following subclause after 14.4:

14.5 Time scale component overflow and underflow

Time scale components described in this document and in ISO 8601-1 are each defined to accept a range of values, some with a defined minimum or maximum value.

A date and time expression can contain time scale components with values outside the acceptable value ranges of those components.

- A date and time expression is considered to have a normalised duration only if it does not contain any time scale component in the state of overflow or underflow.
- A date and time expression is considered to have an “overflow” if it contains at least one time scale component in the state of overflow.

EXAMPLE 1 The expression '1H90M' contains an overflow in the clock minute time scale component, as the meaning of '90M' is equivalent to the expression '1H30M'.

EXAMPLE 2 The expression '1M90S' does not contain an overflow in the clock second time scale component, as the meaning of '90S' cannot be identically expressed in an alternative combination of these two time scale components, given that the clock minute and clock second are not an unequivocally convertible time scale component pair.

- A date and time expression is considered to have an “underflow” if it contains at least one time scale component in the state of underflow.
