## Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of ISO document should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see [www.iso.org/directives](http://www.iso.org/directives)).

ISO draws attention to the possibility that the implementation of this document may involve the use of (a) patent(s). ISO takes no position concerning the evidence, validity or applicability of any claimed patent rights in respect thereof. As of the date of publication of this document, ISO had not received notice of (a) patent(s) which may be required to implement this document. However, implementers are cautioned that this may not represent the latest information, which may be obtained from the patent database available at [www.iso.org/patents](http://www.iso.org/patents). ISO shall not be held responsible for identifying any or all such patent rights.

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see [www.iso.org/iso/foreword.html](http://www.iso.org/iso/foreword.html).

This document was prepared by Technical Committee ISO/TC 85, *Nuclear energy, nuclear technologies, and radiological protection*, Subcommittee SC 5, *Nuclear installations, processes and technologies*.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at [www.iso.org/members.html](http://www.iso.org/members.html).

## Introduction

Uranium in situ leach mining has many unique advantages compared to conventional mining technologies, such as: small investment, short construction period, little production cost, less energy consumption, low labour intensity, high production efficiency, no tailings and waste rock, and minimal impact on the natural landscape. Uranium production by in situ leach has ranked first among various uranium mining/milling methods since 2009<sup>[1]to[5]</sup>, among which the global production of natural uranium produced by in situ leach reached approximately 27 773 tU in 2022<sup>[6]</sup>, accounting for 56 % of the world's natural uranium production (49 355 tU).

Groundwater environmental impacts can be substantial due to in situ leach mining and should be considered throughout planning, operation and remediation<sup>[7]</sup>. In the case of Königstein in situ leaching (Germany), a total of 100 000 t of sulfuric acid was injected with the leaching liquid into the ore deposit. The liquid contains high contaminant concentrations, for example, expressed as multiples of the drinking water standards: cadmium 400x, arsenic 280x, nickel 130x, uranium 83x, etc. This liquid presents a hazard to an aquifer that is of importance for the drinking water supply of the region. Groundwater impact is much larger at the Czech in situ leaching site of Stráz pod Ralskem: 28,7 million m<sup>3</sup> of contaminated liquid is contained in the leaching zone, covering an area of 5,74 km<sup>2</sup>. This zone contains a total of 1,5 million tonnes of sulphate, 37,500 t of ammonium, and others. The contaminated liquid has spread out beyond the leaching zone horizontally and vertically, thus contaminating another area of 28 km<sup>2</sup> and a further 235 million m<sup>3</sup> of groundwater.

Decommissioning and environmental remediation are the last steps in the whole process of site selection, design, operation, and decommissioning of nuclear facilities. Determination of groundwater remediation targets is a key point for in situ leach groundwater remediation<sup>[8]to[10]</sup>. No standards on determination of groundwater remediation targets for in situ leach uranium have been published at the international level.

This document sets out the fundamental principles of determining the groundwater remediation targets for post in situ leach (also referred as in situ recovery) uranium mining. This document is one of a set of International Standards on groundwater remediation for in situ leach uranium mining.

This document is formulated in order to manage the groundwater environment protection of uranium in situ leaching, ensure human health and ecological receptors safety, and standardize the determination of groundwater remediation target values for uranium in situ leaching.

This document provides the basic principles and procedures for determining the groundwater remediation target values for in situ leach uranium mining, including requirements for groundwater environmental investigation, stakeholder engagement, identification of groundwater remediation technology, and determination and adjustment of groundwater remediation target values.
